List of Acronyms

ARM: Administrative Rules of Montana. Agency regulations, standards or statements of applicability that implement, interpret, or set law or policy. DNRC has adopted ARMs that address Forest Management on forested state trust lands.

BA: Basal Area. The cross-sectional area of the bole of a tree measured at breast height, expressed in square feet per acre.

BBF: Billion Board Feet. A unit of measure for timber volume expressed in billions of board feet.

CCRX: Clear-Cut Management Prescription. An aggregate term for even-aged management pathways (EARX) that terminate in a regeneration harvest, which leaves 4 trees per acre (leave trees) as an over-story contribution towards the regenerated stand. These leave trees are not reduced with a second entry harvest.

CE: Central Land Office. A DNRC administrative office that includes all the administrative units from the central part of Montana. Units included in the Central Land Office are Bozeman (BOZ), Conrad (CON), Dillon (DIL) and Helena (HEL).

CT: Commercial Thinning. A silvicultural treatment incorporated into even-aged management pathways (EARX), which calls for a partial harvest that reduces the trees per acre down to a predetermined threshold. Volume removed is considered commercial since harvest is scheduled at an age which should produce merchantable trees. The purpose of this treatment is to reduce the competition between trees for resources, allowing the retained trees to potentially accelerate growth.

DBH: Diameter at Breast Height. A measure of the diameter of a tree at 4.5 feet above ground level (breast height).

DNRC: Department of Natural Resources and Conservation. The state agency tasked with managing the Montana trust lands to create revenue for the beneficiaries, while considering environmental factors and protecting the future income-generating capacity of the land.

EA: Eastern Land Offices. A collective term for the Land Offices and administrative units from the eastern part of Montana. Land Offices included are Southern, Northeastern and Eastern. Units included are Billings (BIL), Glasgow (GLA), Havre (HAV), Lewistown (LEW) and Miles City (MIL).

EM: Eastern Montana. A term used in reference to the Forest Vegetation Simulator (FVS) variant for the eastern parts of Montana (Central and Eastern Land Offices).

EARX: Even-Aged Management Prescription. An aggregate term for management pathways terminating in a regeneration harvest, during which the majority of trees are removed, resulting

in a single-age regenerated stand (single canopy structure). Some of these pathways include options to do pre-commercial and commercial thinning.

FIA: United States Forest Service Forest Inventory and Analysis. A program of the United States Forest Service, tasked with running a continuous national census on forest land, and predicting the future state of forests.

FVS: Forest Vegetation Simulator. A growth and yield simulator developed by the United States Forest Service for predicting the future forest conditions. It was used in the 2015 sustainable yield calculation to predict the future yields from DNRC lands under various management pathways.

GIS: Geographic Information System. A computerized system for storing and analyzing spatial data. GIS was used extensively in the 2015 sustainable yield calculation to establish the location of stands for growth modeling, as well as their participation in various wildlife and habitat constraints.

GORX: Grow-Only Management Prescription. A management pathway with no active management anywhere along the planning horizon (i.e. no regeneration harvest, thinning, or selection harvest).

GZB: Grizzly Bear. A term commonly used in this report, which refers to various habitat constraints applied that mitigate adverse effects to grizzly bears.

HCP: Habitat Conservation Plan. A plan prepared under Section 10 of the Federal Endangered Species Act to conserve threatened and endangered species. The HCP is a 50-year cooperative plan with the United State Fish and Wildlife Service that contains minimization and mitigation measures for grizzly bear, Canada lynx, bull trout, west-slope cutthroat and Columbia red-band trout. These conservation measures are applied to minimize effects to the covered species from implementation of forest management activities. Applicable constraints were developed for these measures and applied in the calculation model.

IE: Inland Empire. A term used in reference to the Forest Vegetation Simulator (FVS) variant for the western parts of Montana (Northwestern and Southwestern Land Offices).

LMA: Lynx Management Area. A key geographic area in the context of DNRC ownership that is of notable importance for lynx. LMAs are delineated zones that contain forested trust lands where increased levels of lynx conservation commitments are applied. Within these areas, records indicate that lynx are likely present (or have been in the relatively recent past) or lands are considered important for maintenance of resident lynx populations.

LP: Linear Programming. A mathematical programming technique used to solve problems that contain a series of linear equations, which can be subdivided into an objective function that needs to be optimized, and a set of constraints that limits the extent of the optimization.

MB&G: Mason, Bruce & Girard. A natural resource management consultancy based in Portland, OR which was hired by the DNRC to perform the 2015 sustainable yield calculation.

MCA: Montana Code Annotated. Codification and compilation of existing Montana state general and permanent law.

MBF: Thousand Board Feet. A unit of measure for timber volume expressed in thousands of board feet.

MMBF: Million Board Feet. A unit of measure for timber volume expressed in millions of board feet.

NW: Northwestern Land Office. A DNRC regional administrative office that includes all the administrative units from the north-western part of Montana. Units included in the Northwestern Land Office are Kalispell (KAL), Libby (LIB), Plains (PLN), Stillwater (STW) and Swan (SWN).

NDY: Non-Declining Yield. A term used in context of harvest scheduling and controlling the period-on-period difference in harvest volumes, where the volume for each planning period is allowed to increase from one period to the next, but not decrease.

OGRX: Old-Growth Management Prescription. An aggregate term for all old-growth management pathways that include a selection harvest (partial harvest). Harvests occur on a periodic basis (30 or 50 years) and trees are selected for harvest based on a basal area target for the stand as a whole, as well as a trees per acre target for large trees (large defined by a DBH threshold). The objective of these management pathways is to allow selection harvest from old-growth stands, while sustaining the ecological condition and maintaining their old-growth status.

OS: Over-Story. The trees that are kept after the regeneration harvest on even-aged management pathways (EARX) for the purposes of aiding the regeneration of the next stand of trees. The composition of the over-story is dependent on the even-aged management objective (CCRX, STRX, or SWRX), as well as the timing and intensity of removal during the second entry harvest.

PCT: Pre-Commercial Thinning. A silvicultural treatment in seedling/sapling stands incorporated into even-aged (EARX) and uneven-aged (UERX) management pathways, which calls for a partial harvest that reduces the trees per acre down to a predetermined threshold.

QMD: Quadratic Mean Diameter. A measure of the diameter at breast-height for the tree of average basal area in a sample of trees.

RMZ: Riparian Management Zone. Under the DNRC HCP and Forest Management Administrative Rules (ARMs 36.11.401 through 36.11.450), an RMZ refers to streamside buffer established when forest management activities are proposed on sites with high erosion risk or on sites that are adjacent to fish-bearing streams or lakes (ARM 36.11.425).

SDI: Stand Density Index. A measure of tree stocking, expressing the degree to which trees are utilizing the available growing space. Calculation is based on the number of trees and the diameter at breast height of the tree with average basal area.

SFLMP: State Forest Land Management Plan. A programmatic plan adopted by DNRC in 1996 that provides the philosophical basis and technical rationale for DNRC's forest management program on state trust lands. The resource management standards contained in the selected alternative were adopted into administrative rules in 2003.

SLI: Stand Level Inventory. The DNRC's central repository for all stand register data. Each record in this database represents a single stand, with a stand defined as a piece of land that is uniform with regards to the properties of its vegetation and is identified through a known stand boundary. These stand boundaries are contained within the agency's Geographic Information System (GIS), which is fully integrated with the SLI.

STRX: Seed-Tree Management Prescription. An aggregate term for even-aged management pathways (EARX) that terminate in a regeneration harvest, which leaves 8 trees per acre (leave trees) as an over-story contribution towards the regenerated stand. On approximately half of the stands treated with this prescription, the leave trees are reduced to 4 trees per acre with a second entry harvest, 10 years after the regeneration harvest.

SW: Southwestern Land Office. A DNRC regional administrative office that includes all the administrative units from the south-western part of Montana. Units included in the Southwestern Land Office are Anaconda (ANA), Clearwater (CLW), Hamilton (HAM), and Missoula (MSO).

SYC: Sustainable Yield Calculation. A calculation that represents the harvest volume that can be sustained over the planning horizon, given the projected stand yields, habitat constraints, and an inventory of standing trees in the final planning period that can theoretically sustain the same harvest volumes beyond the planning horizon.

SWRX: Shelter-Wood Management Prescription. An aggregate term for even-aged management pathways (EARX) that terminate in a regeneration harvest, which leaves 25 trees per acre (leave trees) as an over-story contribution towards a regenerating stand. On approximately half of these stands, leave trees are reduced to 4 trees per acre with a second entry harvest, 20 years after the regeneration harvest.

TPA: Trees per Acre. The estimated count of trees (stems) on one acre of land.

UERX: Uneven-Aged Management Prescription. An aggregate term for management pathways that include a selection harvest (partial harvest). Such harvests occur on a periodic basis (30 or 40 years) and trees are selected for harvest based on a pre-determined DBH distribution. This distribution is an abstraction of what a multi-aged stand (heterogeneous canopy structure) would look like, and trees are selected for harvest in such a manner as to

move the stand closer to this distribution. Some of these pathways include options to do pre-commercial and commercial thinning.

UMZ: Unique Management Zone. Land parcels with unique management considerations, due to their inclusion in Conservation Agreements & Easements, as well as Federal Wild & Scenic River Corridors.

USFS: United States Forest Service. The agency of the U.S. Department of Agriculture charged with managing the national forests.

List of Technical Terms

Commercial Forest Land: Timber land capable of growing commercial crops of trees. Land that can grow 20 cubic feet of timber volume per acre per year.

Cruise: To take field measurements of trees in a timber stand. Cruising is a statistical sampling technique.

Deferred Land: Timber land not managed for timber production due to other administrative uses, topographic constraints, and/or other physical factors, accessibility problems, or high development costs relative to timber values.

Even-Aged Management: A management regime culminating in a final harvest. Trees in the newly regenerated stand will be of a similar age.

Even-flow: A term used in context of harvest scheduling and controlling the difference between subsequent periods in harvest volumes, where the volume for each planning period has to be exactly the same.

Forest Vegetation Simulator (FVS) -A forest growth and yield model developed and maintained by the U.S. Forest Service. FVS provides a platform to simulate and estimate the effects of various forest management activities on forest conditions, growth, and yield. FVS uses geographic variants to estimate potential forest growth for different regions in the U.S. The Inland Empire (IE) and Eastern Montana (EM) variants were used for this calculation.

Grizzly Bear Security Zones: Areas within the DNRC Stillwater Unit intended to provide security for grizzly bears, which generally meet the Interagency Grizzly Bear Committee definition of "Core." For this calculation, the Security Zone Areas were based on land areas identified in a negotiated settlement (August 20, 2015) between DNRC and Plaintiffs in a lawsuit involving the DNRC Forest Management Habitat Conservation Plan. Of the 22,007 acres of security zones identified in the settlement agreement, 20,370 commercial acres were identified and deferred from harvest.

Land Board: The State Board of Land Commissioners consists of Montana's five top elected officials who direct the management of State trust lands administered by the Department of Natural Resources and Conservation.

Maximum Biological Potential: The highest level of timber harvest that could be sustained, assuming all commercial timber land is available for harvest, and optimal management regimes could be implemented. This is a measure used to benchmark the productivity of a forest.

Management Regime: A schedule of specific management actions to be applied to a timber stand over time. Management actions may include activities such as natural regeneration, pre-commercial thinning, commercial thinning, regeneration harvest, selection harvest, etc.

Old Growth: A timber stand is designated as “old growth” if it meets the old-growth minimum criteria found in Green *et al.* (1992) as adopted by the DNRC.

Planning Horizon: The number of years, or planning periods, for which a strategic planning effort makes future predictions.

Second Entry Harvest: The second harvest associated with even-aged management pathways (EARX), where the over-story of trees kept after the regeneration (first) harvest are reduced to the final number of trees per acre.

Sustainable Yield: “...the quantity of timber that can be harvested from forested state lands each year in accordance with all applicable state and federal laws, including but not limited to the laws pertaining to wildlife, recreation, and maintenance of watersheds, and in compliance with water quality standards that protect fisheries and aquatic life and that are adopted under the provisions of Title 75, chapter 5, taking into account the ability of state forests to generate replacement tree growth.” (MCA 77-5-221)

Tariff Equations: Equations that the DNRC uses to calculate Scribner board foot volumes for a tree, given the species, height and DBH of the tree.

Timber Stand: A tract of forest land relatively homogenous with respect to species mix, size and stocking of tree species. The minimum stand size is five acres.

Timber Type: A code assigned to each timber stand describing the existing species mix, size class and stocking class.

Acknowledgements

We at MB&G appreciate the hard work and valuable insight provided by the dedicated professionals at the Montana Department of Natural Resources and Conservation. Mark Slaten, Tim Spoelma, and Ross Baty were especially helpful in assisting with the design of the analysis and providing data. Dan Rogers provided both leadership and encouragement to the planning team. Members of the field review team provided careful review and thoughtful comments.

Finally, we acknowledge the contributions of Dave Mason, founder of our firm in 1921. His early and zealous advocacy for sustainable forest management practices have had long lasting impacts on how our society views and manages our forest resources.

Executive Summary

The Trust Land Management Division of the Montana Department of Natural Resources (DNRC) manages approximately 750,000 commercial forest acres for the benefit of the Common Schools and other endowed institutions. Management activities on those lands focus on providing a consistent and long-term revenue source for the trust beneficiaries, which is generated by selling a consistent annual timber volume. The amount of timber sold annually is determined through a sustainable yield calculation (MCA 77-5-223).

The last sustainable yield calculation was performed in 2015 in conjunction with the acquisition of approximately 67,000 acres of land to the DNRC's timber base. The passage of Senate Bill 154 in the 2013 Montana Legislative Session required DNRC to conduct this calculation, which set a sustainable harvest level of 56.9 million board feet (MMBF) annually. Mason, Bruce, and Girard, Inc. performed that calculation.

Since that last calculation in 2015, DNRC has acquired $\pm 13,000$ acres of former industry-owned timber land, primarily in the Stillwater Unit. Pursuant to state law (MCA 77-5-222), requiring that an independent third party conduct the calculation, the DNRC contracted with Mason, Bruce & Girard in 2019 to perform the calculation.

For this sustainable yield calculation, the DNRC relied on data collected from its own lands in 2014 and 2018 and used FVS growth model calibrations developed by the U.S. Forest Service and MB&G. For this calculation the DNRC also emphasized using the professional expertise of its field staff for several facets of the project, including updating areas deferred from active management, identifying lands suitable for helicopter and cable logging, designing management regimes, and verifying growth and yield projections. The DNRC used the Inland Empire and Eastern Montana variants of the Forest Vegetation Simulator¹, both of which are specific to Montana forests, for growth and yield projections.

For this calculation, MB&G evaluated two scenarios. The first scenario incorporated all of DNRC's commercial timber acres, including newly acquired lands, and all of DNRC's programmatic and operational management constraints, resulting in an annual sustainable harvest level of 68.3 MMBF.

The second scenario was designed to determine the impact of the $\pm 13,000$ recently acquired acres on the sustainable yield. For that scenario, the acquired lands were withdrawn from the model developed for the first scenario where all commercial forest acres were available for management, resulting in an annual sustainable harvest level of 66.8 MMBF and inferring that the addition of those lands contributes 1.5 MMBF to the annual sustainable yield.

For all scenarios, acres identified as suitable only for helicopter logging did not contribute to the annual sustainable yield and were considered to provide an opportunistic amount of volume

¹ Documentation and software available at <https://www.fs.fed.us/fvs/index.shtml>

above and beyond the calculated yields when markets permit. When market conditions are feasible for helicopter logging, those lands could contribute an additional 1.4 MMBF to the annual sustainable yield.

The results of this calculation show an increase of approximately 20 percent in the annual sustainable harvest volume compared to the previous calculation from 2015 (68.3 MMBF vs. 56.9 MMBF). There are several important factors that distinguish this effort from the prior effort and that provide a significant contribution to these results. DNRC carefully examined its inventory data and associated cruise plot data used for growth and yield modeling and found weak correlation between the timber strata as identified in its inventory and as described by the cruise plots for sampled stands. To improve the correlation of inventory and cruise data and therefore the accuracy of the calculation, DNRC re-stratified both its inventory data and plot data into new species groups and stocking classes for this calculation. DNRC also re-evaluated the calibration used in the FVS growth and yield model, and for this calculation used western root disease model calibrations for the IE variant of FVS developed by the U.S. Forest Service, and a calibration developed by MB&G and the Custer-Gallatin National Forest for the EM variant of FVS. DNRC also re-evaluated acres deferred from management in the 2015 calculation and made many of those acres, particularly in the Central and Eastern areas, available for harvest.

Purpose, Need and History

Purpose of and Need for the Sustainable Yield Calculation

The Trust Land Management Division of the Montana Department of Natural Resources and Conservation (DNRC) Forest Management Program manages approximately 930,000 forested acres for the benefit of the Common Schools and other endowed institutions. Of those 930,000 acres, approximately 750,000 acres are commercial forest land. Commercial forest land includes those lands that are dominated by commercial conifer species and have potential productivity greater than 20 cubic feet/acre/year. DNRC manages trust lands to “produce revenues for the trust beneficiaries while considering environmental factors and protecting the future income-generating capacity of the land.”²

On forested trust lands, the DNRC’s management standards and philosophy are guided by the State Forest Land Management Plan (SFLMP)³, associated Administrative Rules (ARM)⁴ and the DNRC’s Forested State Trust Lands Habitat Conservation Plan (HCP)⁵. Management is based on maintaining biodiversity and sustainability, while utilizing active forest management⁶. Annual activities on forested state trust lands are aimed at generating income, monitoring and improving practices, investing in the future productivity of forested stands, and conserving an array of resources.

Revenue from forested state trust lands is primarily derived from the sale of forest products. State law directs the DNRC to sell a consistent amount of timber each year, as determined by the annual sustainable yield calculation, which in turn provides a consistent revenue source for the trust beneficiaries.⁷ State law also requires that the DNRC, under the direction of the State Board of Land Commissioners (Land Board), commission an independent third party to calculate the annual sustainable yield for forested state trust lands at least once every 10 years.⁸ Annual sustainable yield is defined as:

“...the quantity of timber that can be harvested from forested state lands each year in accordance with all applicable state and federal laws, including but not limited to the laws pertaining to wildlife, recreation, and maintenance of watersheds, and in compliance with water quality standards that protect fisheries and aquatic life and that are adopted under the provisions of Title 75, chapter 5, taking into account the ability of state forests to generate replacement tree growth.”⁹

⁹ MCA 77-5-221

Periodic recalculation of sustainable yield is necessary to incorporate changes in management intensity or emphasis, or as new laws and regulations are applied.

In 2019, the DNRC contracted with Mason, Bruce & Girard, Inc. (MB&G) to perform the sustainable yield calculation. Established in 1921, MB&G is a natural resources consulting firm located in Portland, Oregon. MB&G has performed similar calculations for a variety of federal, state, private and tribal landowners across the US. MB&G performed the DNRC's previous three sustainable yield calculations in 2004, 2011, and 2015.

History

Past Sustainable Yield Calculations

DNRC has calculated a sustainable yield six times in the past 40 years. **Table 1.** provides summary information for the five prior calculations.

Table 1: Past Sustainable Yield Calculations

Year	Sustainable Yield	Acres Receiving Management
1983 ¹⁰	50.0 MMBF	399,700
1996 ¹¹	42.2 MMBF	363,769
2004 ¹²	53.2 MMBF	430,784
2011 ¹³	57.6 MMBF	469,159
2015	56.9 MMBF	570,511

The last sustainable yield calculation was completed in September 2015 by MB&G. That study determined that the annual sustainable harvest level was 56.9 MMBF.¹⁴

From FY 1997 through FY 2003, the DNRC based the timber sale program on the 1996 calculation. In 2003, the Legislature directed the DNRC to sell 50 MMBF annually.¹⁵ In 2004, the annual sustainable yield was calculated to be 53.2 MMBF; this calculation also served as the baseline for the no-action alternative for DNRC's HCP. The DNRC based its annual timber sale requirement on the 2004 calculation until 2012 when its HCP was adopted, increasing the annual sustainable yield to 57.6 MMBF. Between 2011 and 2015, DNRC acquired approximately 67,000 acres of commercial forest land, prompting a new calculation to incorporate production from those acres into DNRC's annual sustainable yield. At the same time, the DNRC resolved a lawsuit regarding

¹⁴ MBF – thousand board feet; MMBF – million board feet; BBF – Billion board feet, all in Scribner measure. A typical log truck holds 4-5 MBF.

¹⁵ 77-5-222 MCA, 2003

the HCP that resulted in the creation of “security zones” for grizzly bears in the Stillwater Unit, and the terms of the settlement of that lawsuit were included in the calculation, resulting in an annual sustainable yield of 56.9 MMBF.

The annual timber sale program since 1997 is shown in **Figure 1**.¹⁶ In some years, sold volumes exceeded the basis provided by the sustainable yield calculation due to timber salvage activities following wildfires or insect infestations that required timely entry to capture the value of the standing dead timber, or less frequently due to resale of unsold volume that was offered for sale in prior years.

Figure 1: Volume sold from State Lands, FY 1997-2020 (MMBF, saw timber)

Changes since the 2015 Sustainable Yield Calculation

In the report for the 2015 calculation, MB&G made three recommendations to the DNRC to improve on the efforts made for that calculation as well as previous efforts:

1. Collect cruise information in areas/strata that have not been cruised and collect additional plot data to strengthen future inventory calculations.
2. Improve stand inventory data, particularly stand age and productivity estimates
3. Continue and expand FVS calibration

¹⁶ Note that Figure 1 shows volume sold, not volume harvested. While revenues ultimately flow to the beneficiaries based on harvest, the volume sold is a more direct measure of DNRC annual timber sale effort. Volume sold for FY 2015 is estimated.

In response to those recommendations and to produce improved results over prior sustainable yield calculation efforts for this calculation, DNRC initiated several steps to increase its understanding of conditions on, and affecting forested state trust lands, as well as the quality of its data:

- DNRC expanded on its 2014 cruise information by cruising stands belonging to timber strata in the NWLO, SWLO, and CLO that had no or minimal cruise information. This cruise was conducted in 2018 and included 43 stands with a total of 765 plots, resulting in a grand total of 358 stands and 6,058 plots representing 53 timber strata (not including productivity class designations within strata) in the NWLO, SWLO, and CLO. Approximately 89 percent of acres in the NWLO, SWLO, and CLO are in strata that have at least one stand that has been cruised [the EA area relies on U.S. Forest Service Forest Inventory and Analysis Data (FIA) as the source of tree list data for growth and yield models; DNRC has not conducted any cruise sampling in that area].
- DNRC carefully examined its inventory data and associated cruise plot data used for growth and yield modeling. To improve the correlation of inventory and cruise data and therefore the accuracy of the calculation, DNRC re-stratified both its inventory data and plot data into new species groups and stocking classes for this calculation. This resulted in a significant reduction in the number of timber strata compared to the 2015 calculation, and also necessitated the development of a new set of yield tables for growth and yield modeling.
- DNRC has kept its Stand Level Inventory (SLI) current through monthly updates each year. Updates are based on harvest activities or on re-visitation of individual stands. DNRC also collected new stand-level inventory on its newly acquired acres in the Stillwater and Libby Units in 2019 for inclusion in this calculation.
- DNRC updated its productivity classes to a consistent statewide standard that matches the productivity classes used by the U.S. Forest Service FIA program as opposed to defining separate productivity classes for each Land Office.
- DNRC updated its growth and yield model calibration using western root disease model calibrations developed by the U.S. Forest Service for the IE variant of FVS, and used a calibration developed for the Custer-Gallatin National Forest by MB&G for the EM variant. DNRC also opted to use the IE variant of FVS for the CLO as opposed to the EM variant that was used in 2015; the EM variant is now used only in the EA area. These calibrations resulted in increased growth rates across all Land Offices compared to 2015 and that are in line with published growth rates for Montana as well as anecdotal growth rates from industrial private forest landowners in Montana.
- DNRC undertook measures to update several other data sources, including road and hydrology GIS layers, which resulted in a more accurate representation of the amount and location of those features and their impacts on management.
- DNRC used an ArcGIS online project with its foresters to review and reclassify stands that are deferred from management. For this exercise, DNRC reviewed and revised stand

deferral criteria, resulting in a more accurate representation of stands that are not currently available for management due to factors including topography, wet areas, low productivity, low timber value combined with high development costs, inaccessibility, timber conservation licenses, and other land uses, among others.

Uses & Limitations

This sustainable yield calculation is based on a great deal of spatial and tabular data about the forest. Some of the data are site specific, other data are more generalized. A Forest Management Model was designed to address strategic level questions.¹⁷ Specifically, the model was designed to provide a reasonable and defensible estimate of:

- A sustainable harvest level from DNRC lands, along with associated revenues;
- The interaction between management, and wildlife habitat and water resource constraints; and
- A projection of forest conditions across DNRC lands.

Given the data and effort invested in the modeling effort, it may be tempting to try to use the model for purposes beyond the stated objectives. As discussed below, however, the model has limited spatial capabilities. Readers are cautioned against trying to use the model for more tactical, operational or site-specific tasks. While the model might be used to analyze general management strategies, for example, it should not be used to locate harvests into specific stands or under specific management regimes.

¹⁷ Strategic questions: How should we manage this forest to meet objectives? What kinds of management regimes are most compatible with our objectives? How important are current investments for meeting future harvest objectives?

Tactical questions: Which roads should we build and which stands should we harvest first?

Operational questions: Where should the landing go?

Data and Methods

In this section, we discuss the source data for each component of the 2020 calculation and relevant differences between the models used for the 2020 and 2015 SYCs. Included are a general overview of the modeling approaches describing the main components of the models and their relationship to each other. This is followed by a detailed discussion of the components with emphasis on describing the land information used, how this was compiled into an inventory estimate, growth predictions, and optimization of the sustainable yield calculation.

Overview of the Forest Management Model

The objective of the forest management model is to find the optimum sustainable harvest for the land managed by the DNRC, subject to fulfilling the agency's obligations towards wildlife habitat, water resources, managing the land towards a desired future condition, and the operational constraints inherent to the organization.

The data and methods used in this analysis will be discussed in detail below. In short, the modeling effort consisted of combining the cruise and SLI data through a stratification process into an inventory estimate, which described the current state of the forest. The data from this process were used in FVS in conjunction with management pathways to make future yield projections. These projections were used within a LP modeling framework to optimize the sustainable harvest level subject to meeting wildlife, water resource, and operational constraints.

Land Base

The description of the land base provided estimates of acres, content (what is on these acres) and location (where is it) used in the modeling framework, and it played a pivotal role in stratification, inventory calculation, management pathway allocation and setting the starting condition for the LP optimization model. Within the DNRC Forest Management Program, the SLI is the central repository for all land data.

The Stand Level Inventory (SLI)

The DNRC's Stand Level Inventory is the central repository for all of the agency's stand inventory data. The SLI is contained within DNRC's Geographic Information System (GIS). Each record in the SLI represents a single stand defined by a boundary that has uniform site characteristics (slope, aspect, elevation, habitat type, etc.) and vegetation. The SLI contains approximately 29,800 stand records, of which approximately 27,890 are commercial forested land. Each SLI record contains data describing numerous attributes of each stand; of those, the following were essential to this calculation:

Table 2: List of Key SLI Parameters

Land Office	The DNRC administrative Land Office to which the stand belongs
Unit	The DNRC administrative unit, within a Land Office boundary, to which the stand belongs
Species	A description of timber type, in terms of major species
Size	The existing dominant tree (timber) size in inches
Stocking	The density of trees in the stand expressed as trees per acre
Age	An estimated average age for the stand
Productivity	The expected average productivity of a stand in terms of ft ³ /acre/year
Habitat Type	The stand's habitat type classification following Pfister et al. (1977) ¹⁸
Acres	The net acres contained within the stand

SLI data is typically gathered by directly visiting a stand (“walk-through”) or photo interpretation data gathering. The SLI database used in this analysis was current as of September 2019.

Other Information about the DNRC Commercial Forest Land Base

Several GIS layers were used to incorporate wildlife habitat and operability considerations into the model. The following data were incorporated into the model through a series of GIS overlay analyses:

Table 3: Additional DNRC Forested Land Base Information

Deferred	Acres deferred from management, due to operational issues such as legal access, topography, excessively wet areas, and cabin site leases.
Riparian Management Zone (RMZ)	“No harvest” zones established immediately adjacent to Class 1 streams and lakes in accordance with the DNRC Forest Management HCP.
Unique Management Zone (UMZ)	Conservation Agreement & Easement areas, as well as Federal Wild & Scenic Corridors.
Helicopter Harvest Acres	Stands only operationally feasible to be logged by helicopter.

¹⁸ Pfister, R.D, B.L. Kovalchik, S.F. Arno, R.C. Presby. 1977. Forest Habitat Types of Montana. USDA Forest Service, Gen. Tech. Rep. INT-34, Intermountain Research Station, Ogden, UT.

Cable Harvest Acres	Stands only operationally feasible to be logged using cable (skyline) harvest systems.
Sensitive Watersheds	DNRC parcels that lie within watersheds that are designated as sensitive to increases in water yield. Harvest levels in these watersheds need to be managed within the ARMS and HCP commitments governing cumulative watershed effects.
Grizzly Bear	Two defined land areas exist (1. Recovery Zone, and 2. Non-recovery Occupied Habitat lands) that contain DNRC lands, where distinct constraint sets relevant to habitat management for grizzly bears are required.
Lynx Management Areas	Seven defined areas of notable importance for lynx conservation containing DNRC ownership. Several habitat parameters must be maintained above minimum threshold levels in these areas requiring a specific suite of management constraints.
Potential Lynx Habitat	Stands of appropriate Habitat Type (Pfister et al. 1977) that are, or have the potential to become, lynx habitat, with management actions aimed at attaining habitat attributes.
Bald Eagle Nesting Site	Bald eagle nest locations on or near DNRC lands, which must be managed to maintain the suitability of the site for nesting.

Source of Stand Table Data

For the NWLO, SWLO, and CLO (hereafter NW, SW, and CE) Land Offices, cruise data collected from DNRC land in 2014 and 2018 served as the source data to describe timber strata and develop stand tables for those Land Offices. For the NELO, SLO and ELO (hereafter EA Land Offices), the same FIA data used in the 2014 calculation was used. Descriptions of the cruise design and data collected can be found in Chapter 4 of the 2015 SYC report.

Following MB&G's recommendation in the 2015 SYC report, DNRC collected supplemental cruise data from strata in the NW, SW, and CE areas in 2018 to collect or strengthen information for strata that had no or minimal cruise data. When combined with the cruise data collected for the 2015 SYC, DNRC sampled 358 stands with 6,058 individual plots (Table 4).

Table 4: Number of Stands Sampled and Plots Collected by Land Office

Land Office	Stands Sampled	Plot Count
CE	48	801
NW	184	3,134
SW	126	2,123
Total	358	6,058

DNRC used the same FIA plot data to develop tree lists for DNRC's East-side timber strata that was used in the 2015 SYC.

Stratification of Timber Types

As with the 2015 SYC, a strata-based approach, rather than a stand-based approach, was used to generate both inventory, and growth and yield information for the 2020 SYC. Each stand in the SLI was grouped into a stratum defined by a unique combination of Land Office, species, size class, stocking, and productivity class.

To improve correlation between the cruise information and SLI and produce more accurate inventory and growth and yield model estimates, DNRC re-stratified both the inventory cruise data collected in 2014 and 2018 and its SLI. The forest types defined in the SLI were grouped according to forest types that occupy similar sites (e.g., ponderosa pine and Douglas-fir on warm/dry sites or grand fir, western redcedar, western hemlock, and western white pine forests on moist sites), and the "moderate-" and "well-stocked" classes were grouped into a single "adequate" stocking class. Adjustments were also made to size class information for some stands, particularly stands classified as sawtimber in the SLI that had been previously harvested using even-aged methods and that were dominated by seedling/sapling or poletimber-sized trees.

After the new strata defined by the re-stratification process were applied to the SLI and cruise data, the cruise plot data within a given strata were compiled to produce a tree list representing an average condition. This process did not deliver a tree list for every stratum, because in some cases there were no plot data within certain strata. In such cases, these empty strata were assigned a substitute tree list from a stratum with plot data that were closest in terms of vegetation, with priority given to matching species, size class, and stocking, respectively.

To estimate differences in site productivity within each stratum, low, medium and high productivity variants of each stratum were generated by producing three copies of the tree list for the stratum and then growing each with a different estimate of future growth potential corresponding to low, medium, and high-productivity sites. Estimates of future growth potential were differentiated by using different habitat types and site index depending on the productivity class (see 0).

Timber Cruise Compilation and Initial Inventory Estimate

As described in Section 4.2.3, two sets of cruise data were used to produce tree lists and stand tables for each stratum:

- DNRC SYC cruise data for the NW, SW, and CE Land Offices
- USFS FIA inventory data for the Eastern Land Office.

Using the final version of each set of cruise data, an MBGTools¹⁹ database was built to process the data for each Land Office. All the cruise data was compiled and merchandized using MBGTools utilities. The following merchandizing specifications were specified by DNRC:

- Minimum DBH = 6 inches
- Stump Height = 1.0 foot
- Log Length = 16 feet
- Minimum Top DIB = 6 inches
- Minimum Log Length = 8 feet
- Trim Amount – 2.5 percent
- Observed tree defect from inventory data
- Unseen cull & breakage default value by species
- Scribner Decimal C Short Log Rule

Following cruise compilation for each stratum in MBGTools, the compiled results for each stratum were multiplied by the number of acres in each stratum and aggregated to produce an initial estimate of standing inventory.

Yield Table Development

This section describes the process of calibrating the growth and yield model and applying management actions to the growth predictions to create the yield projections required for the LP model.

FVS Variants

As with the 2015 SYC, FVS was used to predict future forest conditions, growth, and yield associated with various types of management actions. For the NW, SW, and CE Land Offices, the Inland Empire (IE) variant of FVS was selected, and the Eastern Montana (EM) variant was selected for EA Land Offices. Initially, the EM variant was selected for the CE Land Office; however, the results were unsatisfactory for certain strata, so the IE variant was selected for some strata in the CE Land Office despite being outside the geographic range defined for that variant.

¹⁹ MBGTools is a comprehensive software system for stand-based forestry inventory data compilation and management.

Background

All yield tables were created in MBG's YTGTools application. This is a custom application created by MBG, which utilizes FVS to grow tree lists forward on a period-by-period basis.

A period length of 10 years was used, implying that the difference between subsequent model periods represents ten years of growth. The only exception to this was period one, which represented five years of growth (from period zero to period one). The rationale in this was that the yield table for each stratum should represent the average condition over the ten-year time span; by setting the first growth interval to five years, the quantities in the yield tables reflect the periodic mid-point average in all subsequent periods. Each yield table was grown for 20 periods, thereby representing 200 years of growth.

All yield tables were post-processed to perform a gross to net volume adjustment on inventory and harvest volumes using DNRC's tariff equations.

Habitat Types

Forest habitat type information (Pfister et al. 1977) is used extensively in both the IE and EM FVS variants to parameterize site species, site index, and maximum basal area, all of which are crucial determinants of potential growth.

The SLI contains habitat type information for most stands and was used to allocate habitat types to the low, medium, and high productivity classes within each stratum based on the predominance of the habitat types within each stratum. Please see Appendix L: for the final allocation of habitat types.

Productivity Classes and Site Index

Site Index is another means to quantify site quality and potential productivity, and it is described in terms of the expected height of dominant or co-dominant trees at a base or index age.²⁰ It is used in conjunction with habitat type in the IE and EM variants to predict expected future growth.

Determining site index began by assigning a productivity class (Low, Medium or High) to each stand based on its expected average productivity (ft³/acre/year). The expected average productivity for each stand was extracted from the SLI database, while the productivity classes were provided by the DNRC. In the 2015 SYC, productivity classes were defined for each Land Office; however, for the 2020 SYC DNRC chose to define productivity classes at the statewide level using classes that match those used by the FIA program. The productivity classes are differentiated by the potential growth in a stand at culmination of mean annual increment (Table 5).

²⁰ Helms, JA, ed. 1998. *The Dictionary of Forestry*. Society of American Foresters, Bethesda, MD.

Table 5: Productivity Classes (ft³/ac/yr.)

Productivity Class	Low
Low	20 – 49
Medium	50-84
High	85+

Next, the stand level productivity estimates were aggregated up to an area weighted average productivity, for each unique combination of Land Office and productivity class. The resulting weighted productivity averages are shown in **Table 6**.

Table 6: Average Productivity (ft³/ac/yr.)

Land Office	Low	Medium	High
CE	38	56	85
EA	32	–	–
NW	33	69	101
SW	30	67	95

Site index was derived by assigning each SLI stand a potential productivity rating (ft³/ac/yr.) and then calculating the weighted average productivity estimate for each site class and Land Office. Potential productivity was converted to site index (DF site index base age 50) using conversion factors published by Brickell (Int-75)²¹. Results were reviewed for logical consistency within and between Land Offices. The resulting site index values are shown in **Table 7**:

Table 7: Site Index

Land Office	Low	Medium	High
CE	42	50	60
EA	30	50	--
NW	50	55	70
SW	50	55	65

Stand Age

Stand age is not a required parameter for using either variant of FVS, but it is an important parameter for allocating the silvicultural treatments that accompany some management

²¹ Brickell, James E., Equations and Computer Subroutines for Estimating Site Quality of Eight Rocky Mountain Species", Intermountain Forest and Range Experiment Station, USDA Forest Service Research Paper INT-75, 1970, 22 pages.

pathways. In addition, the linear programming model is age-based, and therefore needs to keep track of age throughout the planning horizon to optimize the harvest level subject to the constraints.

The SLI contains an estimate of average age for most stands. These values were used as a starting point to determine age, resulting in an area weighted average age by Land Office, timber size class and productivity class. These age allocations were reviewed by the DNRC for accuracy, and manually adjusted where necessary. For final implementation, these ages were rounded to the closest mid-decade point (15, 25, 35, etc.), which accommodated the five-year growth period between periods zero and one and allowed subsequent ages to fall on full decadal values (20, 30, 40, etc.). Please refer to Appendix M: Strata Starting Age, for more detail regarding age.

Location Code

FVS utilizes geographic location in several ways to determine localized growth rates. One of these mechanisms is the location code, which matches growth to observed growth on a corresponding USFS National Forest. Each stratum was therefore assigned a location code, using the following scheme:

Table 8: Location Codes

Land Office	USFS National Forest	FVS Location Code
CE	Helena (ie)	112 (maps to 116)
EA	Custer (em)	108
NW	Flathead (ie)	110
SW	Lolo (ie)	116

The analytical steps described in section 4.2.5 resulted in a tree list for each stratum at each productivity class level. The final step before taking these tree lists into FVS was to assign each combination of strata and productivity class with a habitat type, site index, age and location code. These parameters were the result of the analytical processes described in sections 4.2.6.3 through 0.

Growth Model Calibration

At this time, DNRC does not have sufficient information regarding growth rates on its land that could be used for growth and yield model calibration. For the 2020 SYC, DNRC selected calibrations for FVS developed by outside sources. For the IE variant, DNRC used a series of FVS keyword files designed to simulate varying levels of western root diseases on forest growth and

yield that were developed by personnel in the U.S. Forest Service²². For the EM variant, DNRC used an FVS calibration developed by MB&G and the Custer-Gallatin National Forest.

The first set of yield tables consisted of a complete set of grow-only tables (not inclusive of any management treatments such as pre-commercial thinning, commercial thinning and selection harvest) that established a reference point for future calibration by focusing on growth without the influence of active management. These tables were reviewed by a team of DNRC foresters and adjustments were made to either the selected root disease keyword file and/or habitat type until results fell into an acceptable range of expected growth. Productivity classes were also properly ordered within each stratum (i.e.—predicted volumes/growth on low productivity did not exceed those on moderate productivity sites, and moderate did not exceed high). After the full set of grow-only yield tables was complete, a set of yield tables reflecting the application of management activities was produced. At that point, MT DNRC developed factors to adjust volumes reported by FVS, using published growth rates from the FIA program for areas within each Land Office (Appendix O: Growth Rates by Land Office), and aligned with the distribution of acres in each productivity class relative to other Land Offices. These factors were applied to both grow-only and regime yields for the appropriate Land Office. The factors applied were as follows: CE—0.71, EA—1.46, NW—0.96, SW—0.75. Following application of those factors, calibration of FVS was complete.

Management Regimes

Three types of management pathways were formulated for the 2020 SYC: even-aged prescriptions (EARX), uneven-aged prescriptions (UERX), and old growth prescriptions (OGRX). The EARX incorporate a regeneration harvest removing most of the overstory in a single harvest with the objective of regenerating a new age class of trees, while the UERX incorporate a partial harvest of the overstory on a repeated cutting cycle. For old-growth strata in the NW and SW area, OGRX were developed that incorporate an uneven-aged harvest with residual tree targets aimed at maintaining old growth status. Some EARX pathways included a precommercial thinning (PCT) treatment modeled as a thin-from-below (remove smallest trees until target is reached) and/or commercial thinning (CT) modeled as a weighted thin (remove equal proportions from all DBH classes until target is reached). Minimum harvest thresholds for both tractor- (ground) and cable- (skyline) based systems in each Land Office were applied so all thinning treatments falling short of the threshold were skipped (Table 9).

Table 9: Minimum harvest thresholds by Land Office (Mbf/ac)

Land Office	Tractor	Cable
CE	2.0	5.0
EA	0.5	6.0
NW	1.0	3.0

²² <https://www.fs.fed.us/foresthealth/applied-sciences/fvs-models/index.shtml>

SW	1.0	3.5
----	-----	-----

Three different types of EARX pathways were developed: clear-cut prescriptions (CCR_X), seed-tree prescriptions (STR_X) and shelter-wood prescriptions (SWR_X). These three types were distinguished by the amount of over-story that was retained after regeneration harvest, with CCR_X retaining 4 trees per acre (TPA), STR_X 8 TPA and SWR_X 25 TPA. These types were further subdivided by the type of management treatments applied, which varied the inclusion and timing of PCT, CT, and overstory removal. The availability of these pathways to individual strata was defined by Land Office, forest type (species), size class, productivity class. A detailed summary of all the EARX pathways can be found in Appendix D: Management Pathways.

Two different types of UERX pathways were developed for forests occupying dry and moist/wet sites. Eligibility for these types was determined by Land Office and forest type. Both UERX pathways simulated selection harvest by periodically removing trees every 30 or 50 years according to a target DBH distribution, depending on prescription type. The target distributions were generated by defining the total BA, the Q-factor for the distribution, the DBH range and the DBH class size. A tiered approach was then used to incrementally reduce BA in each entry until the target level was reached. A detailed summary of all the UERX pathways can be found in Appendix D: Management Pathways, and Appendix E: Selection Harvest Reversed J-Curves, contains a detailed description of the tiered approach used to incrementally reduce BA. The UERX also included the ingrowth of young trees following a selection harvest, simulating the development of regeneration and understory development following harvesting. The tree lists used for ingrowth were the same as those used for the 2015 SYC.

The OGR_X were formulated in a similar manner to the UERX and consisted of periodic selection harvests that reduced the trees to a minimum BA threshold. In addition, the residual trees had to contain a certain number of large individuals defined by a minimum DBH threshold. Periodic entries ranged from 30 to 50 years, depending on old growth type. A detailed summary of all the OGR_X pathways can be found in Appendix D: Management Pathways.

Regeneration Yields

Regeneration yield tables are required to fully model the application of even-aged regimes (EARX). The EARX regimes result in a complete stand replacement after final harvest, with age resetting to zero, resulting in a transition from the yield table for the existing stand to a new yield table representing the regenerated stand.

For the 2020 SYC, regeneration yield tables were based on the existing adequately-stocked size class 7 (seedling/sapling) stratum for a given species group. All records for trees greater than 5" were removed from the existing size class 7 stratum to compose a new tree list reflecting trees expected to regenerate following harvesting. Large trees representing the remaining overstory associated with each of the EARX groups by stratum (CCR_X—4 trees/acre, STR_X—8 trees/acre,

SWRX—25 trees/acre) were added to the regenerating trees to compose the full tree list for the regeneration yield table. For the STRX and SWRX pathways that included overstory removal (OSR), OSR was applied as a thinning treatment to leave four remaining overstory trees following the OSR harvest. OSR is not applied in the CCRX group. For the STRX pathways that included overstory removal (OSR), 4 of the 8 overstory trees were designated for removal, and for the SWRX, 21 of the 25 overstory trees were designated for removal, resulting in 4 remaining leave trees for each group following OSR.

When transitioning from existing to regenerated strata following the application of EARX, the assumption was made that poorly stocked strata would regenerate as adequately stocked strata. In some cases a species change was also implemented to represent expected natural processes and DNRC's management toward desired future cover types. These species²³ changes are summarized in **Table 10: Regeneration Species changes**.

Table 10: Regeneration Species changes

Existing Species	CE	EA	NW	SW
DPMC	DPMC	DPMC	n/a	n/a
GFRC	n/a	n/a	GFRC	GFRC
LP	LP	LP	LP	LP
NS	DMPC	DPMC	WLDF	PPDF
OGW1	n/a	n/a	PPDF	PPDF
OGW4	n/a	n/a	WLDF	WLDF
OGW6	n/a	n/a	SFC	SFC
PPDF	n/a	n/a	PPDF	PPDF

SFC	n/a	n/a	SFC	SFC
SFM	n/a	n/a	SFM	SFM
WLDF	n/a	n/a	WLDF	WLDF

For the regeneration yield tables, all of the PCT and CT options were made available in addition to the over-story treatments described above.

²³ DPMC – Douglas-fir/ponderosa pine/mixed conifer, GFRC – grand fir/western redcedar/western hemlock/western white pine, LP – lodgepole pine, NS – non-stocked, OGW1 – West-side Old Growth Type 1, OGW4 – West-side Old Growth Type 4, OGW6 – West-side Old Growth Type 6, SF – Engelmann spruce/subalpine fir, SFC –Engelmann spruce/subalpine fir/whitebark pine cold site, SFM –Engelmann spruce/subalpine fir moist site, WLDF – western larch/Douglas-fir

Formulation of the Montana Forest Management Model

The following sections describe the general structure of the optimization model, followed by a detailed discussion of the various components.

Structure of Forest Management Optimization Model

For the 2020 SYC, the optimization model used for the 2015 calculation was applied, with some modifications. This model uses a linear programming (LP) formulation that is well suited to strategic/tactical level harvest optimizations, since optimization solutions can typically be formulated through a system of linear equations. In addition, given a feasible problem, the LP will always solve to the absolute optimum, which ensures that the greatest volume possible solution is always found. The LP model used for this SYC was built in Remsoft's Spatial Planning System.

The main structure of the model consists of four components: analysis areas, actions and transitions, yield projections, and objectives plus constraints. Analysis areas describe the existing condition of the land, as well as alternatives that could be realized in the future. Actions and transitions are responsible for placing land onto various management pathways and converting existing conditions into future conditions. Yield projections quantify the contribution that one acre of land in a given condition would make to various parameters being tracked. These parameters take on several forms, ranging from timber volume to wildlife habitat, and are used to calculate various outputs used in the objectives and constraints component of the model. Objectives and constraints are the model elements respectively used for optimizing the model and constraining the solution to be within certain parameters. For this SYC the objective was to maximize the total harvest volume across the planning horizon, while the constraints limited the management activities and required various habitat thresholds to be maintained. DNRC explored an option maximizing present net value (NPV) across the planning horizon but testing with that objective function produced essentially no difference compared against maximizing NPV.

Model results were reported by planning period, with one period representing 10 years. The planning horizon was 20 periods, resulting in the model scheduling activities for the next 200 years.

Analysis Areas

The analysis area used for this study is defined as all commercial forest land on State Trust Lands throughout Montana, partitioned into administrative units and areas of special consideration. Analysis areas describe both the existing condition of the land, as well as the future options. As such this section of the model is initialized through an imported GIS layer, while the future options are created through a series of actions and transitions. The GIS layer used in this SYC was based on one provided by the DNRC. This layer essentially contained all the stand boundaries (coded for Land Office, unit, species, size, stocking and productivity class), intersected with the

boundaries of various operational and wildlife features (deferred acres, grizzly bear, lynx management areas, etc.). MBG passed this GIS layer through several processes to convert the data into thematic layers, each of which describes a unique feature, that is compatible with the LP model. A total of 25 themes were created in this way. Table 11 provides a description of each of these themes, as well as whether it was ultimately used in the model. Appendix C: Acres in the Forest Management Model, contains a summary of the acres in various themes subdivided by thematic codes.

Table 11: LP Model Thematic Layers (Themes)

Theme	Name	Description	Used
1	Strata ID	A four-part code, denoting the Land Office, species, size and stocking of the stratum that the stand belongs to.	No
2	Land Office	The Land Office that the stand belongs to.	Yes
3	Unit	The administrative unit that the stand belongs to.	Yes
4	Species	The species code used by the stratum to find the appropriate yield table. Not necessarily the same as the one in Strata ID.	Yes
5	Size	The size code used by the stratum to find the appropriate yield table. Not necessarily the same as one in Strata ID.	Yes
6	Stocking	The stocking code used by the stratum to find the appropriate yield table. Not necessarily the same as one in Strata ID.	Yes
7	Productivity Class	The stratum productivity class.	Yes
8	Start Age	The age of the stratum in period zero.	No
9	Deferred	Designates the land parcel as deferred or not.	Yes
10	Rx	The management pathway allocated to the land parcel. All start off on grow-only (E++++GO).	Yes
11	Timing	The timing option associated with the given Rx that was selected. Created the option to delay the start of the treatments associated with a management pathway.	Yes
12	Rotation	Denotes whether the land parcel has existing or regenerated tree cover.	Yes
13	Sensitive Watershed	Denotes whether a land parcel is in a sensitive watershed or not, as well as the name of the watershed.	Yes
14	UMZ	Designates whether the land parcel is within a unique management zone or not.	Yes
15	Logging System	Designates whether the land parcel is within an area requiring helicopter, tractor, or cable logging.	Yes
16	RMZ	Designates whether the land parcel is within a riparian management zone or streamside management zone or not.	Yes

Theme	Name	Description	Used
17	GZB Visual	Designates whether the land parcel is within a grizzly bear visual buffer or not.	Yes
18	GZB Class A	Designates whether the land parcel is within a grizzly bear Class A area or not, as well as the name of the Class A area.	No
19	GZB Security Zones	Designates whether the land parcel occurs within one of seven Grizzly Bear Security Zone located on Stillwater Unit or not.	Yes
20	GZB Subzone	Designates whether the land parcel is within an HCP grizzly bear Management Subzone on the Swan River State Forest or not, as well as the identifying number of the subzone.	No
21	LMA	Designates whether the land parcel is within a Canada lynx management area (LMA) or not, as well as the name of the LMA.	Yes
22	Potential Lynx	Designates whether the land parcel is flagged as potential Canada lynx habitat or not.	Yes
23	Eagle	Designates whether the land parcel is part of a known bald eagle nesting area or not.	Yes
24	OG Recruit	Designates whether the land parcel could be recruited into OG or not.	No
25	OG Current	Designates whether the land parcel is currently OG or not.	Yes

Several themes featured in the 2015 SYC model architecture were not directly used for calculations in the 2020 SYC, including GZB Class A, GZB Subzone, and OG Recruit. These themes were retained to allow comparison to SYC 2015 or in future models to re-enable the functionality.

In addition to the thematic layers described above, the model also required the surface area (acres) of each land parcel and the age at period zero. Age was obtained from the strata data, while the area was already calculated in the GIS layer. Once all of this data was complete, the LP model imported the data and created existing development types. Development types are a way for the model to aggregate data and reduce the computational overhead. This aggregation is done on unique combinations of thematic codes and age (i.e.—all land parcels with the same combination of thematic codes and age would have been grouped into the same development type). Many separate polygons may share a development type, and the model operates on the acres within a development type aggregated across relevant polygons. In total, the model imported 747,280 acres from 47,235 polygons, of which 9,966 polygons (21.1%) were less than 1 acre in area. From this the model created 6,048 development types representing the existing land.

Actions & Transitions

A series of actions and transitions were incorporated into the model to generate the various management pathway options that the model could utilize. These actions and transitions generated additional development types, collectively called future development types. In total, 183,648 development types were generated, of which 177,600 (96.7%) were future development types.

Two main forms of actions and transitions were used. Occurring only in the first period was an action to re-assign each development type from its initial grow-only trajectory onto a potential management pathway. An action and transition were created for every unique combination of management prescription and timing option. The actions were used to filter out those acres that possessed thematic codes appropriate for the action being considered, while the transitions placed the acres onto the new prescription and timing option.

The second set of actions and transitions determined when a regeneration harvest would occur for the even-aged regimes. These could occur anywhere along the planning horizon, given that enough harvest volume was available (see **Table 9**) and the minimum harvest age of 80 years had been reached. In addition, the actions also filtered the acres to apply the regeneration harvest only to those acres which had the appropriate thematic codes. The transitions were responsible for taking acres from their existing yield table and placing them onto the regenerated yield table, by changing the appropriate thematic codes. In some cases, this meant a change in species and stocking codes. In all cases this meant resetting age to zero and changing size class to seedling-sapling (size class 7).

Most transitional elements were retained from the 2015 model. For example, currently older existing strata set to even-aged management were allowed to select regeneration pathways that may have differed from their original assignment, staying within the broader silviculture method (e.g. STRX, followed by STRX with CT).

In addition, to reduce model size and solve times while maintaining flexibility to explore management scenarios, only permissible development types were created. For example, only LP and SF in the NW, SW, and CE Land Offices were eligible for CCRX, so no other strata were included in the CCRX action. Some scenarios like BioGross and BioNet required access to CCRX, while others restricted CCRX based on thematic components.

Several new action-transition classes were introduced with this model:

1. Regimes including a PCT or CT can be conducted economically on gentle topography, so actions specifying either of these methods were limited to Tractor ground via Theme 15, Logging System.
2. Minimum harvest volumes (**Table 9**) were imposed by Land Office, so each action was specified for a single Land Office if the harvest threshold was unique, or by Land Office aggregates of the harvest threshold was shared.

3. STRX and SWRX are to be managed as 50% with OS removal and 50% with OS retention. Any action specifying a transition to these even-aged pathways was modified by a percentage allocation, setting half of the acreage to removal and half to retention.

Yield Projections

Yield projections in this model represent the contribution of one acre of land in a given planning period to harvest volume and standing inventory. Yields can represent harvest volumes, interpreted as to wildlife habitat values, or converted to revenues. In terms of LP modeling, yield projections can be described as the coefficients that are associated with variables tracking the number of acres allocated to a given development type in a given period. Yield projections are therefore specified for a specific development type (or group of development types) in a specific period. A total of 3,650 yield tables were developed through this process, each with 20 yield projections representing each decade in the planning horizon. Additional information about the number and distribution of yield tables can be found in **Table 12**.

Table 12: Existing and Future Yield Table Counts by Prescription

Development Type	Rx Type	Silviculture	Count
Existing	GORX	---	227
	EARX	CCRX	87
		STRX	672
		SWRX	661
	UERX	Dry	364
		Moist	129
	OGRX	W1	56
		W4	152
		W6	86
Future	EARX	CCRX	32
		STRX	640
		SWRX	544
Total			3,650

The following yield projections were associated with these yield tables:

- Age in years
- Standing inventory in MBF/Acre before harvest, after defect and tariff equations
- Timber volume removed in MBF/Acre through commercial thinning and selection harvest, after defect and tariff equations
- Standing inventory of Douglas-fir and western larch in MBF/Acre before harvest, after defect and tariff equations (DF)

- Standing inventory of grand fir and western hemlock in MBF/Acre before harvest, after defect and tariff equations (HF)
- Standing inventory of ponderosa pine in MBF/Acre before harvest, after defect and tariff equations (PP)
- Standing inventory of western redcedar in MBF/Acre before harvest, after defect and tariff equations (RC)
- Standing inventory of Engelmann spruce and lodgepole pine in MBF/Acre before harvest, after defect and tariff equations (SP)
- Standing inventory of western white pine in MBF/Acre before harvest, after defect and tariff equations (WP)
- Standing inventory of subalpine fir, mountain hemlock and whitebark pine in MBF/Acre before harvest, after defect and tariff equations (WW)
- Basal area in ft²/Acre after harvest
- Total stems per acre after harvest
- Stems per acre larger than or equal to 13" DBH after harvest
- Stems per acre larger than or equal to 17" DBH after harvest
- Stems per acre larger than or equal to 21" DBH after harvest
- A PCT flag, used in certain outputs to determine if a PCT harvest occurred or not
- Valid yield table flag, used to prevent the model from assigning acres to development types that do not have a valid yield table

The matter of overstory removal was resolved differently in this model versus the 2015 version. Previously, a generic overstory removal yield was provided by stratum, and all CCRX, STRX, and SWRX pathways received OS removal. In the current version, the OS volume is modeled directly into the yield table. If OS removal is to occur, then the thinning volume represents the OS, and it is removed if this volume exceeds a minimum 1.0 Mbf/ac. If OS retention is specified, then the OS volume remains in the tree list and those trees continue to influence growth rates in the residual stand. Structure of the residual overstory was comparable to 2015, where STRX retaining 8 TPA for two periods and removed 4 TPA at final harvest; SWRX retained 25 TPA for two periods and removed 21 TPA at final harvest. In all pathways, 4 TPA remained permanently.

Another important difference from the 2015 model was the interpretation of the yield for regeneration harvest types. Previously, the regeneration harvest and the separate stratum level OS removal volume were combined into a harvest at a single time point. The 2020 SYC, in contrast, continues to use the volume for regeneration harvest types to represent the harvested timber at the time a regeneration treatment is initiated, but the OS removal, if specified, occurs two periods later. This approach accurately represents the volume removal over time. Minimum harvest volume was determined by the actions section (see § 0 and **Table 9**), and the regen harvest yield was set to zero when stand age was less than 80 years.

Yields for the 2015 SYC used uncalibrated FVS variants and UERX built to a TPA target, while the 2020 SYC used a different FVS calibration, WRD modifiers, and UERX built to BA targets. In

general, 2020 UERX yields rivaled or exceeded the most productive even-aged regimes. Whereas the 2015 LP model favored EARX and required threshold limits on EARX to control this tendency, the 2020 LP model favored UERX. The mechanisms from the 2015 model to limit EARX were repurposed in the 2020 model to limit UERX. DNRC relied on observed silviculture frequency and estimated application of UERX in the SFLMP to support limiting UERX to less than 40% of the acreage.

Economic data were also incorporated into the LP model through a series of yield projections. Stumpage revenues were used in both the 2015 and 2020 SYC models to represent economic value of the harvested timber, with average stumpage updated through 2019 for the 2020 SYC. Average bid price (\$/Mbf) on sales and permits, weighted by volume, were provided by the DNRC on a Land Office basis for the period from 2015 to 2019 for use in the 2020 SYC (Table 13). These values were in nominal terms. These values were incorporated into a stumpage revenue for each Land Office. In early LP model experiments, it was demonstrated that maximizing Harvest Volume resulted in an identical SYC to maximizing Net Present Value using these stumpage rates. As this model assumes an implicit logging cost, optimizing revenue and volume is functionally equivalent.

Table 13: Stumpage (\$/Mbf) for the 2015 SYC and updated for 2020 SYC.

Area	2014 Stumpage/MBF	2020 Stumpage/MBF
CLO	146.42	114.80
Eastern Land Offices	70.71	34.25
NWLO	239.37	189.80
SWLO	221.29	159.80

Objectives and Constraints

Within the LP modeling framework, objectives are the mechanism whereby results are optimized, while constraints limit the solutions to pre-defined thresholds. An LP solution will therefore always contain an objective function that has been optimized, subject to meeting the constraints that were established.

The objective of the 2020 SYC was to maximize total harvest volume, where total harvest volume was defined as the sum of the harvest volume in each period across the planning horizon (20 periods). Periodic harvest volume was calculated as the sum of the periodic harvest volumes from even-aged pathways and uneven-aged pathways. The sum of the periodic harvest volumes from even-aged pathways was inclusive of volumes from commercial thinning, regeneration harvest (net volume from first harvest) and over-story removal volume (second harvest volume).

All these volumes were inclusive of the volume from helicopter acres, which implies that the helicopter acres participated in the objective function.

To ensure equity between current and future beneficiaries of the forested State trust lands, it is important to maximize the short-term harvest that can be sustained over the 200-year planning horizon. However, it is also important to know whether future harvests could be sustained at a higher level, perhaps because of investments in stand improvement, forest regulation, etc. The LP objective function, therefore, must emphasize the short-term harvests, while also recognizing benefits from long term improvements. This dual objective is achieved by discounting the harvest of each period. We used a discount rate of 2%. A typical discount rate of 4% or 5% might be used for forestry investments in which the primary objective is maximized value. For State-owned forestlands serving a variety of constituents, a lower value of 2% is acceptable. Moreover, a 2% discount rate likely captures the growth rate at the time when many DNRC stands are harvested. The difference in annual sustainable yield between 2% versus 4% discount rate in a maximum production scenario is only 93.15 MMbf versus 93.55 MMbf, or just 0.4 MMbf. When all DNRC management constraints are imposed, the differential due to discount rate selection was not meaningful.

Several constraints were established to limit the optimal solution to pre-determined limits. All constraints were applied on a per period basis. The purpose of these constraints can be classified as either non-declining yield (NDY), protection of wildlife habitat, water resources, application of silvicultural regimes, operational limits, or LP error control.

A single NDY constraint was established to ensure that the optimum harvest levels can be maintained over the length of the planning horizon. In this case a non-declining flow constraint (period-on-period increase allowed, but never decreasing) was used, as opposed to an even-flow constraint (equal period-on-period volumes). The rationale behind this was that it could be theoretically possible for the model to harvest more volume in the future as new and improved development types became available. Using the NDY constraint would make this extra volume accessible, since the SYC level can increase (not decrease); while the even-flow constraint would make it inaccessible since no fluctuation is allowed. The NDY constraint also excluded the volume from helicopter logging acres. The fact that these acres were included in the objective function resulted in them being scheduled for harvest, but not contributing to the sustainable yield level. Their contribution is therefore purely opportunistic, which is consistent with current operating and market conditions.

Whereas the 2015 LP model featured an overall NDY constraint, the 2020 updated model applies the NDY constraint over each Land Office. Sustaining yields at the Land Office level was deemed an important goal for 2020, rather than allowing fluctuation by Land Office, which even in the case of Statewide NDY could mean declining yields in some periods for certain Land Office(s).

Table 14: Non-Declining Yield Constraint

Constraint	Group	Description
Non-Declining Yield	NDY	Total harvest volume exclusive of volume from helicopter acres can increase period-on-period but cannot decrease.

The wildlife habitat, water resource, and management constraints were directed towards protecting water resources by maintaining water quality, maintaining the levels of existing wildlife habitat, or limiting the intensity of management on existing habitat, or requiring certain levels of habitat development. The wildlife habitat, water resource, and management constraints are summarized in Table 15: Wildlife Habitat, Water Resource and Management Constraints. Please refer to section 0 for more detail on each constraint theme. Appendix B: Compatibility Matrix, contains additional information pertaining to the constraints. All listed endangered, threatened, sensitive, and big game species for which DNRC has management obligations under administrative rules were considered during the development of constraints for the calculation. Appendix N: Wildlife Habitat , contains information and notes regarding constraint development, and inclusion/exclusion rationale for all species considered in this study.

Table 15: Wildlife Habitat, Water Resource and Management Constraints

Constraint	Group	Description
Snags	BIO NET	Requirements for the retention of snags and snag recruits were addressed in the design of the management regimes for this calculation. Volume necessary for snag maintenance was constrained as a part of the residual volumes and trees per acre retained in each allowable prescription. See Appendix D: Management Pathways.
Deferred	DEF	No treatment was assigned to deferred acres. All deferred acres (Theme 9 = Y) must be assigned to grow-only management pathways.
RMZ	RUMZ	All riparian management zone (RMZ) and Streamside Management Zone (SMZ) acres (Theme 16 = Y) must be assigned to grow-only management pathways.
UMZ	RUMZ	No unique management zone (UMZ) acres (Theme 14 = Y) can be assigned to even-aged management pathways.
Swift BPA	RUMZ	Acres in the BPA portion of the Lazy-Swift acquisition in the Stillwater Unit must be assigned to uneven-aged management pathways.

Constraint	Group	Description																				
Old Growth	OG	At least 8% of acres must meet the old-growth criteria for the NW and SW Land Offices on a unit basis, and 4% of acres must meet the old-growth criteria for the CE Land Office on a unit basis. Old-growth acres were contributed from two sources, namely existing old-growth and recruitment. Existing old-growth acres are existing acres classified as either OGW1, OGW4 or OGW6, prior to receiving an even-aged harvest. Recruitment acres are those acres not currently classified as existing old-growth but that met the old-growth criteria at a future point in the planning horizon. For the NW and SW Land Offices these acres could be recruited into either OGW1, OGW4 or OGW6, with the following criteria:																				
		<table><tr><td>Group</td><td>Species</td><td>Age</td><td>BA</td><td>TPA</td></tr><tr><td>OGW1</td><td>PPDF</td><td>160</td><td>60</td><td>8 @ 21"</td></tr><tr><td>OGW4</td><td>GFRC, SFM, WLDF</td><td>170</td><td>80</td><td>10 @ 21"</td></tr><tr><td>OGW6</td><td>LP, SFC</td><td>170</td><td>60</td><td>10 @13"</td></tr></table>	Group	Species	Age	BA	TPA	OGW1	PPDF	160	60	8 @ 21"	OGW4	GFRC, SFM, WLDF	170	80	10 @ 21"	OGW6	LP, SFC	170	60	10 @13"
		Group	Species	Age	BA	TPA																
		OGW1	PPDF	160	60	8 @ 21"																
		OGW4	GFRC, SFM, WLDF	170	80	10 @ 21"																
		OGW6	LP, SFC	170	60	10 @13"																
For the CE Land Office recruitment acres had to meet the following criteria:																						
<table><tr><td>Species</td><td>Age</td><td>BA</td><td>TPA</td></tr><tr><td>DPMC</td><td>180</td><td>50</td><td>5 @ 17"</td></tr></table>	Species	Age	BA	TPA	DPMC	180	50	5 @ 17"														
Species	Age	BA	TPA																			
DPMC	180	50	5 @ 17"																			
The age used in these classifications were average stand age, as opposed to the age of the oldest trees used in Green <i>et al.</i> ²⁴ , and will therefore be lower than the published criteria.																						
Sensitive Watersheds	SEN	No more than 36% of acres in sensitive watershed areas may be younger than age 40 years.																				
GZB Visual Buffers	GZB	Only uneven-aged management pathways are available. No even-aged management pathways in grizzly bear visual buffers (Theme 17 = Y)																				
GZB Security Zones	GZB	All Grizzly Bear Security Zone acres in Stillwater Unit (Theme 19 = Y) must be assigned to grow-only management pathways.																				
Lynx Management Area LM1	LMA	At least 65% of acres in each LMA must meet canopy cover criteria, which is defined as 180 TPA when age < 40 years, or BA 60 when age >= 40 years.																				
Lynx Management Area LM2	LMA	No more than 15% of acres (per period) in each LMA can receive a regeneration harvest from an even-age pathway.																				
Lynx Management Area LM31	LMA	At least 20% of acres in each LMA must be in the saw-log size class, with BA at least 60, and must possess inventory in either HF, SP, or WW (see pages 38-39 for definitions of these species groups).																				
Lynx Management	LMA	Limit PCT to 12,000 acres per period across all LMA's, allocated proportional to each LMA based on LMA acres.																				

²⁴ Green, P, J. Joy, D. Sirucek, W. Hann, A. Zack, and B. Naumann. Old-Growth Forest Types of the Northern Region. USDA Forest Service, Northern Region, Missoula, MT, 1992.

Constraint	Group	Description
Area ITP		
Potential Lynx Habitat	POT	On non-LMA lands, at least 65% of acres flagged as potential lynx habitat (Theme 22 = Y), must meet canopy cover criteria, which is defined as ≥ 180 TPA when age < 40 years, or BA 60 when age ≥ 40 years.
Bald Eagle	EAG	All bald eagle nesting site acres (Theme 23 = Y) must be assigned to either uneven-aged or moist-site management pathways, as well as maintain 60 BA.

The purpose of the silvicultural regime constraints was to steer the land base towards the desired condition by limiting the acres that can be allocated respectively to even- and uneven-aged management regimes. These limits tie-in with the management allocations defined in the yield projections.

Table 16: Silvicultural Regime Constraint

Constraint	Group	Description
Even-Age Rx	EAR	Acres allocated to CCRX, STRX, SWRX and UERX cannot exceed the allowable thresholds established for each species and pathway group by DNRC administrative Unit (see Appendix K: Silvicultural Regime Acre Constraints).

The operational limits constraint limited the amount of harvest acres from cable-based harvesting and harvest volume from helicopter acres to levels that are feasible considering market limitations assessed over the last 20 years.

Constraint	Group	Description
Cable	HEL	Total harvest acres from cable ground cannot exceed 18% of the periodic harvest acres for each period
Helicopter	HEL	Total harvest volume from helicopter acres (Theme 15 = Y) cannot exceed more than 2% of the periodic harvest volume for each period exclusive of volume from helicopter acres (NDY volume).

The LP error control constraint prevented the model from allocating acres to development types that were ineligible, with ineligibility defined as development types without a yield projection for growth.

Constraint	Group	Description
Valid Yield	VAL	All acres must be assigned to a yield table with a valid flag value (1).

Results

Qualifications

The LP model used in this sustainable yield calculation can produce detailed stand-level results; however, these results should not be interpreted as indicators of how each stand should be managed, and what could be expected from each stand along its management pathway since the data used to run these models were aggregated by strata. The inventory data used in this analysis were collected from plots distributed over a range of stands, which were aggregated and mapped into strata, resulting in an average condition for each stratum. The results represent the average condition across a range of stands within a given stratum, as opposed to the condition within a particular stand. Furthermore, the objective of this study was to determine a strategic direction for the DNRC in terms of sustainable annual harvest. The results of this study should be interpreted at the strategic planning level, since site-specific operational constraints were not considered in this analysis.

The interpretation of the model results should, however, not be limited only to the annual harvest level, since it is also important to examine the factors that contribute towards a given sustainable harvest level. In this regard it is essential to take note of the management pathways that were selected by the model, and the importance of these pathways in achieving the calculated harvest level. It would be inappropriate to conclude that all acres should be managed exactly like the modeled acres. However, if a general shift towards managing along a given group of pathways is observed in the model results, then it should be considered for incorporation into the DNRC's tactical and operational selection of harvest treatments that are applied on the ground.

Discussion of Model Results

The final runs of the LP model were conducted at a Land Office level where the model is solved in four separate parts (one for each Land Office or Land Office aggregate), as opposed to a statewide approach with all acres optimized in a single model. In the 2015 SYC, early versions of the calculation were performed in four discrete LP models and the statewide result was composited from the summary of the four separate models. The final 2015 SYC was defined at the statewide level with no NDY by Land Office. In contrast, the 2020 SYC is constructed as a single LP model with a separate NDY constraint declared for each Land Office, so that statewide constraints can still be imposed without leading to model infeasibilities. The NDY by Land Office approach restricts the number of options that the model can select, resulting in slightly lower yield outputs for the statewide land base. DNRC managers chose to select the outputs from the Land Office level to provide an increased level of certainty and minimize fluctuation in Land Office harvest planning target levels given DNRC's current operating environment, to ensure that harvest planning targets in each Land Office reflect the present availability of timber within that

Land Office, and to prevent over- or under-harvesting in certain Land Offices as a result of other Land Offices compensating for planned volume from other Land Offices.

MB&G modeled two scenarios for the 2020 SYC. The first included all commercial forest acres and management constraints to determine annual sustainable yield, and the second withdrew newly acquired acres in order to determine the impact of recent land acquisitions.

Scenario 1 – Fully Constrained Model

In this scenario, all commercial forest acres were available for management subject to the model constraints described in Section 4.3.5. The model was run at the Land Office level and in a step-wise manner, incrementally adding constraints to assess their impact. These incremental steps are discussed and illustrated in the following sections and Figure 2. With all constraints applied (EAG model), a total of 583,889 acres were allocated to management regimes (included in solution), and 163,391 acres were excluded from management. Under this scenario a harvest level of 68.3 MMBF/Year can be maintained.

Figure 2: Sequential Reduction in Harvest Volume by Constraint

GO – Grow Only

During the grow-only run all constraints were switched off, and the model was forced to send all acres to no-management pathways by maximizing the acres in no-management. The results were used to assess growth, inventory and the ability of the model to meet constraints. The average

growth across the state was 123 Bf/Acre/Year. Growth rates observed at the Land Office level were 171 Bf/Acre/Year for the NW, 117 Bf/Acre/Year for SW, 52 Bf/Acre/Year for CE and 85 Bf/Acre/Year for EA. Inventory (standing volume) started at 4.4 BBF in period zero, and increased to 15.0 BBF by the end of period 20.

BIO GROSS – Maximum Biological Potential

The purpose of this model run was to determine the highest biologically achievable harvest level by removing all constraints. Instead of using the non-declining yield constraint, an even-flow constraint was used in this model run. The harvest volume included leave trees, meaning that the over-story component associated with even-aged pathways, which is normally left standing after a regeneration harvest, was harvested and reported in the harvest volume. The resulting model returned a sustainable harvest of 91.4 MMBF/Year. Inventory increased over time to 4.7 BBF by period 20. On this run 4,481 acres were allocated to no-management, while 742,799 acres received a pathway with active management. The model had the option to schedule these acres but elected not to do so since they did not contribute to an increase in the harvest level.

BIO NET – Leave Tree and Snag Requirements

The purpose of this model run was to show the impact of the leave trees, which include snags, snag recruits, and other un-harvested over-story trees, on the biological potential. It is exactly the same as BIO GROSS, with exception that the leave tree volumes are removed from the sustainable harvest level. As such it shows the decrease harvest volume attributable to the leave trees. The resulting model returned a sustainable harvest of 85.7 MMBF/Year, a decrease of 6.4%. Inventory decreased over time to 4.1 BBF at period 20. This run allocated 2,018 acres to no-management, while 745,262 acres received a pathway with active management.

DEF – Deferrals

The purpose of this model run was to show the impact of the deferred acres on the sustainable harvest level. All deferred acres are limited to grow-only pathways, resulting in 92,055 acres being removed from managed pathways and assigned to grow-only pathways. The resulting sustainable harvest level was 74.9 MMBF/Year, a decrease of 12.5%. Inventory increased over time to 5.7 BBF at period 20. On this run, 112,050 acres were assigned to no-management, while 635,230 acres received a pathway with active management. The no management acres resulted from the deferred acres that were added to this run, plus a portion of the no management acres that were carried over from the BIO GROSS and BIO NET runs.

RMZ/UMZ- Riparian and Unique Management Zone Constraints

This run showed the impact of RMZ and UMZ acres on the sustainable harvest level. The constraints associated with these acres call for no-management on the RMZ and SMZ acres, and

no even-aged management on the UMZ acres. There are a total of 30,284 RMZ acres, and 3,617 UMZ acres. The resulting sustainable harvest level was 71.2 MMBF/Year, a decrease of 5.0%. Inventory increased over time to 6.1 BBF at period 20. On this run, 135,719 acres were assigned to no-management, while 611,561 acres received a pathway with active management. The no management acres resulted from the RMZ acres that were added to this run, plus the no management acres that were carried over from the DEF run.

OG – Old Growth Constraints

This run showed the impact of constraints associated with OG, which called for 8% OG on each unit in the NW and SW Land Offices, and 4% OG on each unit in the CE Land Office. Existing amounts of old growth in some Units were below the targeted amounts of 8% for NW and SW or 4% for CE, due to the effects of past disturbances including wildfires, forest insect and disease outbreaks, and past timber management. In those Units, as with the 2015 SYC, the old growth constraint was adjusted to require that each Unit currently below the intended target percentage meet that percentage by the same period that the grow only model run was able to meet the constraint. For all units currently below the intended percentage, the grow only model met the percentage requirement in period 5, so the constraint was adjusted to require units below the intended percentage to meet the constraint by period 5. This required the model to maintain existing old growth in accordance with the management regimes applicable to old growth stands while also assigning management pathways to non-old growth stands that facilitated their development into old growth in a sufficient amount to meet the Unit's percentage requirement by the period required, which ensured that the intended old growth amount was met as quickly as possible. The target old growth acres for each unit are shown in Table 17.

Table 17: Old Growth Target Acres per Unit

Land Office	Unit	Target Acres
CE	BOZ	764
	CON	188
	DIL	1,136
	HEL	2,172
NW	KAL	4,008
	LIB	2,398
	PLN	3,975
	STW	9,834
SW	SWN	4,111
	ANA	2,072
	CLW	5,316
	HAM	1,813
	MSO	6,534

The resulting sustainable harvest level was just below 70.5 MMBF/Year, a decrease of 0.05%. Inventory increased over time to 6.2 BBF at period 20. On this run, 135,874 acres were assigned to no-management, while 611,406 acres received a pathway with active management.

HELI – Helicopter Harvest Constraint

The helicopter harvest constraint limited the volume that can be harvested from helicopter acres, by capping the helicopter harvest volume to 2% of the total harvest volume within any given time period (exclusive of helicopter volume). The helicopter volume is seen as opportunistic, and it is therefore excluded from the NDY constraint, but included in the objective function. In addition to the helicopter constraint, this scenario introduced a constraint to limit the acreage of cable logging to not more than 18% in any period. The sustainable harvest level was 70.5 MMBF/Year, a decrease of 0.9%. The associated threshold helicopter harvest volume was 1.4 MMBF/Year (i.e., when available, the model could harvest a maximum of 1.4 MMBF/Year from helicopter acres). Inventory increased over time to 6.1 BBF at period 20. On this run, 136,122 acres were assigned to no-management, while 611,158 acres received a pathway with active management.

EAR – Even-Aged Harvest Constraint

The even-aged harvest constraint limited the number of acres that could be managed under CCRX, STRX, SWRX, in accordance with estimated amounts described in the SFLMP and ARM aimed at applying appropriate silvicultural treatments in reasonable proportions by cover type. **Table 18** shows the constraint levels used. The resulting sustainable harvest level was 69.6 MMBF/Year, a decrease of 0.05%. Inventory increased over time to 6.2 BBF at period 20. On this run, 152,096 acres were assigned to no-management, while 595,184 acres received a pathway with active management.

Table 18: Threshold Acres for EAR Constraint

Rx Group	Threshold Acres
CCRX	48,471
STRX	114,479
SWRX	190,193
UERX	242,040
GORX	152,097
Total	747,280

SEN – Sensitive Watershed Constraint

The purpose of this run was to show the impact of the sensitive watershed constraints, which limited the amount of acres less than age 40 years to 36% of the sensitive watershed acres. This target was imposed for all sensitive watersheds to limit the minimum acres of age classes less

than 40 years to 39,900 acres. The resulting sustainable harvest level was 69.7 MMBF/Year, a decrease of 1.2%. Inventory increased over time to 6.2 BBF at period 20. In this run, 149,545 acres were assigned to no-management, while 597,735 acres received a pathway with active management.

5.2.1.10 GZB –Grizzly Bear Habitat Constraints

This run showed the impact of the Grizzly Bear constraints, including the Grizzly Bear Visual Buffer and the Grizzly Bear security zones, on the harvest level. The visual buffers totaled 4,978 acres, while the security zones totaled 20,370 acres of commercial forest. The resulting sustainable harvest level was just under 68.4 MMBF/Year, a decrease of 0.05%. Inventory increased over time to 6.4 BBF at period 20. On this run, 163,857 acres were assigned to no-management, while 583,423 acres received a pathway with active management.

LMA – Canada Lynx Management Area Constraints

The purpose of this run was to show the impact on the harvest level of HCP constraints applied within the LMAs. This constraint consisted of various subsets of constraints, each dealing with a different aspect of Lynx habitat (LM1, LM2, LM31, and ITP). The acreage thresholds associated with these constraints are shown in Table 19. The resulting sustainable harvest level was 68.4 MMBF/Year, a decrease of 1.8%. Inventory increased over time to 6.4 BBF at period 20. In this run, 167,222 acres were assigned to no-management, while 580,058 acres received a pathway with active management.

Table 19: LMA Constraint Targets

LMA	<u>LM1</u> - Retain 65% Suitable Habitat	<u>LM2</u> - Restrict Suitable Habitat Conversion to 15% per Decade	<u>LM31</u> - Retain 20% Winter Foraging Habitat	<u>ITP</u> - Pre-Commercial Thinning Cap
Coal Creek (CC)	9,323	2,152	2,869	1,019
Garnet (GA)	5,632	1,300	1,733	616
Stillwater East (SE)	23,794	5,533	7,377	2,622
Seeley Lake (SLA)	7,728	1,783	2,377	845

Swan	33,219	7,666	10,221	3,632

POT – Suitable Canada Lynx Habitat Constraint on Scattered Lands

This constraint required the maintenance of suitable habitat with ample cover on at least 65% of all total potential habitat acres, at a Land Office level outside of LMA boundaries. The target acres for each Land Office associated with this constraint are shown in Table 20. The resulting sustainable harvest level was 68.4 MMBF/Year. There was no detectable reduction in sustainable

harvest level associated with this constraint. Inventory increased over time to 6.5 BBF at period 20. In this run, 173,263 acres were assigned to no-management, while 574,017 acres received a pathway with active management.

Table 20: Suitable Lynx Habitat Target Acres

Land Office	Target Acres
CE	32,935
EA	3,783
NW	48,896
SW	24,306

EAG – Bald Eagle Habitat Constraint

The results of this run showed the impact of bald eagle habitat constraints on the harvest level. This constraint called for habitat in eagle nesting and primary use areas to be maintained on 6,675 acres with basal area exceeding 60 ft²/acre. The model was unable to meet the threshold requirement of 6,675 acres due to the fact that some stands did not meet the minimum requirement of 60 ft²/acre of BA from the onset (period 0), despite being classified as bald eagle habitat; while others never grew beyond 60 ft²/acre of BA. The primary cause of this is that the model utilized strata level yield tables, which represented the average condition of all stands in the strata (i.e., the actual stand probably achieved the threshold value, and hence the fact that it was classified as bald eagle habitat). With no management (grow only), the model was able to meet the constraint on a statewide basis by period seven, so in order to provide the model with a workable solution that incorporated management, the starting period for the constraint was changed to period seven and the threshold was reduced to 6,650 acres to maintain the greatest level of constraint possible. Although the eagle habitat constraint was intended to emphasize uneven-aged management pathways with sustained basal area exceeding 60 ft²/acre, this constraint conflicted with the cap imposed on uneven-aged acres by the EAR constraint (\$0). No additional acreage could be diverted to uneven-aged at this point, so the model sought the eagle habitat acres in even-aged silvicultural regimes that met the criteria of exceeding 60 ft²/acre at all times. These even-aged pathways are effectively managed as uneven-aged because they are not harvested. Consequently, the final sustainable harvest level was 68.3 MMBF/Year, a decrease of 0.1% despite an increase in the total acres under active management. Inventory increased over time to 6.5 BBF at period 20. In this run, 163,857 acres were assigned to no-management, while 583,889 acres received a pathway with active management.

Scenario 2 – Impact of Acquired Lands

A model run was conducted to determine the impact of the acquired acres on the sustainable yield. For this scenario, the acquired lands were withdrawn from the Fully Constrained Model

(Section 5.2.1), resulting in an annual sustainable harvest level of 66.8 MMBF and inferring that the addition of those lands contributes 1.5 MMBF to the annual sustainable yield.

Recommendations for Future Calculations

The 2020 SYC represents the latest refinement to a harvest scheduling model devised in 2004. During the 2015 SYC update, MB&G identified several avenues to improve the result. The DNRC has implemented aspects of the 2015 recommendations, which we will review in the next section. During the last five years, other developments have emerged that justify new recommendations, with which we close this section.

Revisiting Recommendations from 2015 SYC

Each of the recommendations below are condensed from the 2015 SYC report, with further comments regarding DNRC progress toward each objective and opportunities for updates.

Inventory program: Implement annual inventory program first focused on capturing data from unrepresented or under-represented strata, eventually to update all strata on a regular basis.

Progress: DNRC undertook a significant effort to re-stratify existing stands by species composition and forest structure more suited to the ownership. Additional inventory data from 2018 were included in the 2020 SYC. The 2015 report recommended expansion of inventory to the Eastern Land Office, but that has not yet been possible.

Update 1: Extend inventory to the Eastern Land Office and update the tree lists for each EA stratum, including testing FVS calibration to anticipate impacts of change to tree lists.

Update 2: Extend inventory to strata that are currently represented by substitutions— affects 115 strata across all of the Land Offices.

Augmenting SLI with habitat typing and stand age: Refine the habitat typing and stand age assignment in the SLI, recognizing that defining stand age is challenging for uneven-aged management types that are widely represented in DNRC ownership.

Progress: The habitat type code is among the strongest drivers of growth in the Inland Empire and Eastern Montana variants of FVS. The re-stratification undertaken for the 2020 SYC required new habitat code assignments for all strata. Similarly, re-stratification necessitated new age assignment by stratum.

Update 1: Both habitat type and age are effectively acting as FVS calibration proxies in the 2020 SYC, and may not derive from observations for all strata due to the new stratification method. Habitat can be assigned during annual inventory efforts.

Update 2: The set of stand ages used in the 2020 SYC was inherited from the 2015 SYC and may be refined to better represent the age classes of the new strata.

Calibrate FVS more specifically for DNRC lands: The out-of-the-box FVS IE and EM variants are typically unsuited to particular locations and should be calibrated.

Progress: The 2020 SYC adopted FVS calibrations developed for the Custer Gallatin and Helena Lewis and Clark National Forests, as well as Western Root Disease modules devised for several productivity classes.

Update 1: The EM variant of FVS should be best suited for the CE and EA Land Offices, but the calibration was not always acceptable without strata substitutions, habitat reassignment, or conversion to IE variant. For a future SYC, the DNRC annual inventory program could be leveraged to provide tree list data helpful for a DNRC-specific EM calibration.

Update 2: Both EM and IE variant yield forecasts required additional modifications even after application of CG, HLC, and WRD key word sets, but could be further calibrated to DNRC specifications using standard key word modifiers.

Additional Recommendations

The DNRC has already implemented various elements of the recommendations from the 2015 SYC report. Changes to stratification in the 2020 effort will necessitate a review of the habitat type and age assignments prior to the next SYC update. Beyond the updates recommended in the previous section, which were chiefly a continuation of the ongoing programs, there are several areas where DNRC may consider new approaches.

The revised stratification scheme in the 2020 SYC is more appropriate, but sampling intensity was not explicitly discussed in the 2015 report. Certain strata in certain Land Offices (NW, SW) produce the bulk of the timber volume and value. If there is an economic imperative for revenue generation rather than simply proportionally representing acreage, sampling could be emphasized in Land Offices or districts where this is the case.

Each LP from 2004, 2015, and 2020 was constructed as a stratum-based model, but the DNRC GIS consists of individual stands, which could afford the opportunity to upgrade to a stand-based model, assuming sufficient resolution on inventory. Budget may not support a traditional timber cruising program to update the SLI at the time scale necessary for a stand-based model, but remote sensing approaches may be an option in the near future. The DNRC system relies on the combination of SLI, tree lists, and FVS, however, it is not clear that the USFS itself is anticipating that FVS will remain its yield projection system of choice.

Rapidly declining costs for acquisition of detailed satellite imagery and LiDAR data are leading the USFS to look to these total coverage data types to describe their entire ownership. As a State agency, DNRC could be in a good position to collaborate with USFS on data acquisition and analysis. A remote sensing approach could gain relevance as USFS devotes only limited resources to maintenance and active development of FVS. Proportionally greater emphasis is being placed on remote sensing data collection, suggesting a strategic shift from mechanistic individual-tree modeling to recurrent and complete "wall to wall" observations. The modeling

framework to project future yields and stand structure from these remote sensing products has not been developed, however, and it is unclear what form these will ultimately take.

MB&G Certification

I certify that to the best of my knowledge and belief that:

- The statement of facts contained in this report is true and correct.
- The reported analyses, opinions, and conclusions are limited only by the reported assumptions and limiting conditions and reflect my personal, unbiased professional analyses, opinions and conclusions.
- We have no present or prospective interest in the resource that is the subject of this report.
- Engagement in this assignment was not contingent upon developing or reporting predetermined results.
- Compensation for completing this assignment is not contingent upon the development or reporting of a predetermined result or direction in result that favors the cause of the client.
- Significant professional assistance was provided to the persons signing this certification as follows: and Jessica Burton-Desrocher.

1 Appendix A: Summary of Model Runs

1.1 Fully Constrained Model

The following charts show selected results from the final Fully Constrained LP model run.

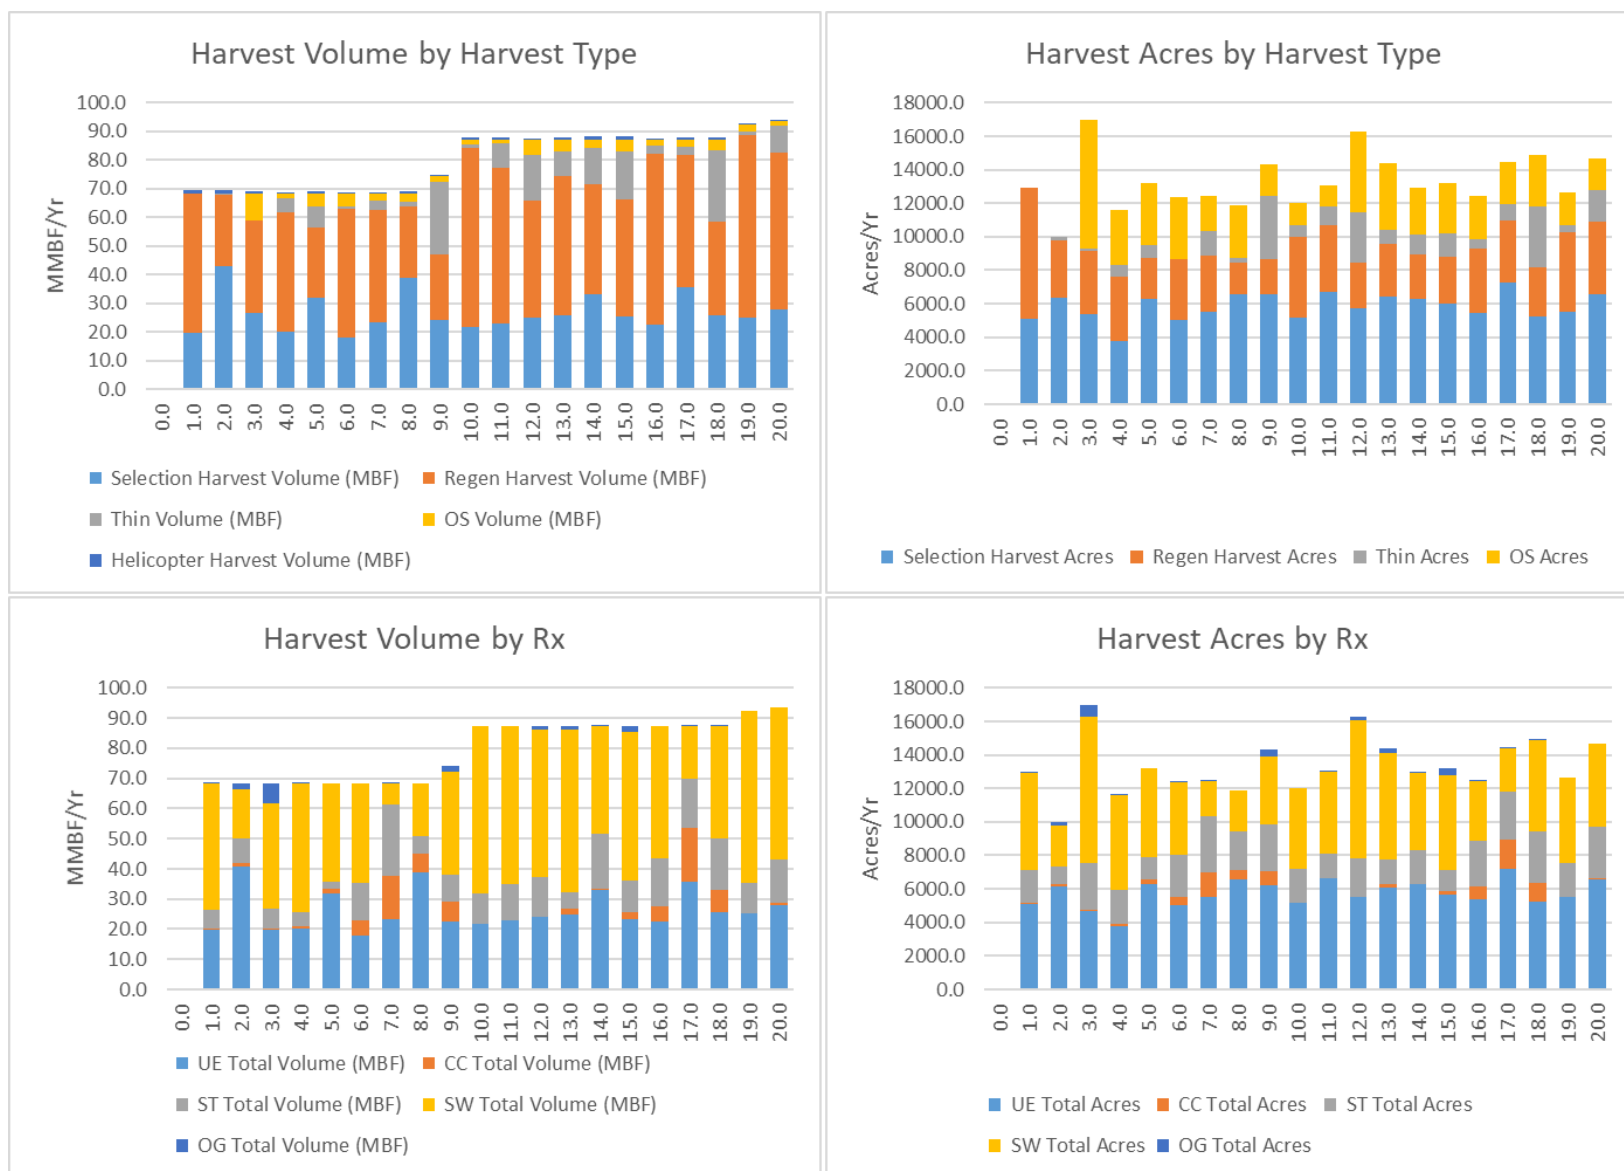

Figure 3: Fully Constrained Model Results – Page 1

Figure 4: Fully Constrained Model Results – Page 2

2 Appendix B: Compatibility Matrix

The following matrix shows the relationship between the various LP model thematic layers and the major management pathway groups

- GORX. Grow only management pathways with no active management or silvicultural treatments.
- CCRX. Even-aged management pathway (EARX) that terminates in a clear-cut regeneration harvest.
- STRX. Even-aged management pathway (EARX) that terminates in a seed-tree regeneration harvest.
- SWRX. Even-aged management pathway (EARX) that terminates in a shelter-wood regeneration harvest.
- UERX. Uneven-aged management pathway with multiple selection harvests.
- OGRX. Old-growth management pathway with multiple selection harvest entries, which aim to maintain old-growth status.

In this table a “?” indicated that the given thematic layer was not limiting with regards to the pathway, while an “N” indicates that only areas coded as not part of the thematic layer could participate in the pathway. Additional details for the land office, species and productivity themes are provided in Appendix D.

3 Appendix C: Acres in the Forest Management Model

The following tables show the acres present in various thematic layers, and how the acres were classified within each. The thematic layer represented in each table is labeled in the top right corner of each table. The data within each table is organized as cross-tabulations, with thematic values in the rows and land management unit in the columns (except for the first table which has land office in the columns).

The table “Unit Acres” contains a cross-tabulation of management unit acres by land office. Table 21 shows the various codes used for unit and land office:

Table 21: Key to Codes for Land Office and Unit

Land Office	Name	Unit	Name
CE	Central	ANA	Anaconda
EA	Eastern	BIL	Billings
NW	North-Western	BOZ	Bozeman
SW	South-Western	CLW	Clearwater
		CON	Conrad
		DIL	Dillon
		GLA	Glasgow
		HAM	Hamilton
		HAV	Havre
		HEL	Helena
		KAL	Kalispell
		LEW	Lewiston
		LIB	Libby
		MIL	Miles City
		MSO	Missoula
		PLN	Plains
		STW	Stillwater
		SWN	Swan

The thematic codes used in the “Strata Acres” table consists of three components, namely species (vegetation type), size class and stocking. The code “WLDF7A” therefore represents the strata for western larch/Douglas-fir species (WLDF), seedling-sapling size class (7), and adequate stocking (A). Species is represented by

a two-, three-, or four-digit code, while size and stocking are always represented by a single digit. The old-growth strata (OGW1, OGW4 and OGW6) do not follow this classification scheme and are only represented by their four-digit codes. Please refer to section 0 for a definition of the old growth codes. Table 22 shows the various codes used for species, size and stocking:

Table 22: Key to Codes for Species, Size and Stocking

Species	Land Office	Name	Size	Name	Stocking	Name
DPMC	CE, EA	Douglas-fir/Ponderosa Pine/Mixed Conifer	6	Non-Stocked	N	Non-Stocked
GFRC	NW, SW	Grand fir/Western Redcedar/Western Hemlock/Western White Pine	7	Seedling - Sapling	A	Adequate
LP	ALL	Lodgepole Pine	8	Pole-Timber	L	Low
NS	ALL	Non-stocked	9	Saw-Timber		
PPDF	NW, SW	Ponderosa Pine/Douglas-fir				
SF	CE, EA	Engelmann spruce/Subalpine fir				
SFC	NW, SW	Engelmann spruce/Subalpine fir/Whitebark Pine Cold Site				
SFM	NW, SW	Engelmann spruce/Subalpine fir Moist Site				
WLDF	NW, SW	western larch/Douglas-fir				

Some thematic layers were labeled with either a “yes” (Y) or “no” (N) value to indicate whether a given acre was part of the constraint or not. Therefore, in the tables below a row value of “In (Y)” was used to flag the acres that were part of the thematic layer, while “Out (N)” was used to flag the acres outside of the thematic layer. For instance, in the Deferred Acres table, the acres associated with the “In (Y)” row were deferred, while the acres associated with the “Out (N)” row were not deferred.

Finally, the following codes in Table 23 were used to identify acres in sensitive watersheds and lynx management areas (LMA).

Mason, Bruce & Girard, Inc.

Table 23: Key to Codes for Sensitive Watersheds and LMA's

Sensitive Watershed	Name	LMA	Name

4 Appendix D: Management Pathways

The following tables show the combinations of land office, species and productivity class that were eligible for each management pathway (Rx). These tables also show the types of silvicultural treatments that each pathway was eligible for. These treatments can be classified as either pre-commercial thinning (PCT), commercial thinning (CT), or selection harvest (Sel. or uneven-aged). PCT treatments were defined in terms of age of treatment and after-harvest trees per acre (TPA). CT treatments were defined in terms of earliest age of treatment and after-harvest trees per acre (TPA). The selection harvest for the uneven-aged pathways (UERX) were defined in terms of earliest age of treatment, residual TPA target and re-entry period, while the old-growth selection harvests (OGRX) were defined in terms of after-harvest BA, TPA larger than a threshold diameter at breast height (DBH), and re-entry period. The even-aged pathways (EARX) were also defined in terms of the number of leave trees associated with each harvest intensity type (CC, ST, or SW).

Each of the management pathways were labelled with a unique 8-digit Rx code, with each digit describing a different aspect of the pathway. This allowed each pathway to be labeled with a unique code that could be used as a reference for the silvicultural treatments within the pathway. The following table describes the composition of the Rx codes in further detail:

Table 24: Key to the Rx Codes

Digits	Group	Code	Definition
1	Strata Type	E	Existing Strata
		N	Future (Regeneration) Strata
2	PCT	+	No PCT
		2	PCT at Age 20
3 to 4	CT and Sel. Harvest	++	No CT or Selection Harvest
		1T	One CT to a TPA Target
		MB	Multiple Selection Harvests to a BA Target
5	Fertilization	+	No Fertilization
6 to 7	Rx Type	CC	EARX with Clear-Cut Regeneration Harvest
		ST	EARX with Seed-Tree Regeneration Harvest
		SW	EARX with Shelter-Wood Regeneration Harvest
		UD	UERX on Dry Site
		UM	UERX on Moist Site
		W1	OGRX on W1
		W4	OGRX on W4
		W6	OGRX on W6
8	Overstory Removal	N	No Overstory Removal Harvest
		X	Overstory Removal Harvest Option Not Available
		Y	Overstory Removal Harvest

5 Appendix E: Selection Harvest Reversed J-Curves

The reversed J-Curves for UERX were developed through a series of trials. Initially only three curves were defined, one each for dry, moist and wet sites. Each of these curves had a Q-factor, a DBH range from zero to 24, a DBH class size of 4", and retained 2 TPA larger than 24". All of them also used a 30-year re-entry period. Implementation of these curves showed unacceptably large BA reductions following selection harvests, often resulting in tree lists that were well below their BA target and unsustainable with regards to volume. The solution was to follow a tiered approach, which incrementally decreased the BA target until the desired level was reached (Don't try to get to future desired condition in one step). This approach worked well for moist, resulting in two tiers each. For moist sites the first tier targeted 115 BA with a Q-factor of 1.8, while the second tier targeted 80 BA with a Q-factor of 1.4. For dry sites more trials were needed. A three-tier approach with a 40-year re-entry period was investigated, which worked well for NW and SW strata. For these strata the first tier targeted 85 BA with a Q-factor of 1.7, the second tier targeted 65 BA with a Q-factor of 1.5, and the third tier targeted 45 BA with a Q-factor of 1.2. The CE and EA strata however still showed residual BA falling well below the target. Following more trials, a two-tier approach was adopted for these strata using a DBH range between zero and 20", and 1 TPA larger than 20". For these strata the first tier targeted 80 BA with a Q-factor of 2.8, while the second tier targeted 50 BA with a Q-factor of 2.2.

Table 29: Reversed J-Curve Definitions

6 Appendix F: Summary of SYC Law from Montana Code Annotated

77-5-221. Definition. As used in 77-5-222, 77-5-223, and this section, "annual sustainable yield" means the quantity of timber that can be harvested from forested state lands each year in accordance with all applicable state and federal laws, including but not limited to the laws pertaining to wildlife, recreation, and maintenance of watersheds, and in compliance with water quality standards that protect fisheries and aquatic life and that are adopted under the provisions of Title 75, chapter 5, taking into account the ability of state forests to generate replacement tree growth.

History: En. Sec. 1, Ch. 517, L. 1995.

77-5-222. Determination of annual sustainable yield. (1) (a) On July 1, 2013, the department, under the direction of the board, shall commission a new study by a qualified independent third party to determine, using scientific principles, the annual sustainable yield on forested state lands. The department shall direct the qualified independent third party to determine the yield pursuant to, but not exceeding, all state and federal laws.

(b) A new study may be commissioned by the department, under the direction of the board, at any time during the 10-year period provided for in subsection (2).

(2) A determination of annual sustainable yield under subsection (1) must be reviewed and re-determined by the department, under the direction of the board, at least once every 10 years.

History: En. Sec. 2, Ch. 517, L. 1995; amd. Sec. 1, Ch. 440, L. 2003; amd. Sec. 1, Ch. 288, L. 2013.

77-5-223. Annual sustainable yield as timber sale requirement -- review. The annual sustainable yield constitutes the annual timber sale requirement for the state timber sale program administered by the department. This annual requirement may be reduced proportionately by the amount of sustained income to the beneficiaries generated by site-specific alternate land uses approved by the board based on a determination under 77-5-222.

History: En. Sec. 3, Ch. 517, L. 1995 ; amd. Sec. 2, Ch. 288, L. 2013.

Figure 57: SW Old Growth Acres (Missoula) – Fully Constrained Model

11 Appendix K: Silvicultural Regime Acre Constraints

The following table shows the percentage of acres that was allowed to be allocated towards CCRX, STRX, SWRX and UERX for each unique combination of unit and species. These percentages were used by the silvicultural regime constraint in the LP model to set a threshold value for each management pathway type.

Table 30: Silvicultural Regime Constraint Percentages

Species	Regime	Unit				
		ANA, CLW, HAM, MSO	EA/CE:BIL,LEW,HAV,GLA,MIL	CE: DIL	KAL, LIB, PLN	STW, SWN

12 Appendix L: Calibration Keyfiles, Habitat Types, Substitute Tree Lists, and Substitute Yield Tables

FVS variants, calibration keyfiles, and habitat types used to differentiate among high, low, and moderate productivity classes are shown in Table 31. For strata that did not have associated cruise data or insufficient cruise data, the stratum whose tree list and/or yield table served as substitute are also listed. Habitat type codes in Table 31 refer to the habitat types and codes as described in Pfister et al. (1977).

Table 31: FVS Calibration Keyfile, Habitat Types, Substitute Tree Lists, and Substitute Yield Table for each Stratum

13 Appendix M: Strata Starting Age

Age is difficult to determine stands on DNRC land, since most of them are uneven-aged. However, age is an important element in structuring the management pathway and compiling the linear programming model; therefore a starting age was assigned to each stratum by land office, size class, and productivity class as shown in Table 32.

Table 32: Starting Age by Land Office, Size and Productivity Class

Land Office	Size	Productivity Class		
		Low	Medium	High
CE	6	0	0	0
CE	7	15	15	0
CE	8	65	65	0

SW	9	115	115	115
SW	W1	155	145	---
SW	W4	---	155	155
SW	W6	165	165	165

14 Appendix N: Wildlife Habitat Constraints

The DNRC has an obligation towards maintaining and creating habitat for various wildlife species through a number of administrative rules. The following tables list the constraints applied or considered, along with the relevant ARMs and HCP commitments, as well as the rationale behind their inclusion or exclusion from the modeling effort.

Table 33: Wildlife Constraints Developed from Forest Management ARM's and DNRC HCP

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
Grizzly Bear	HCP, GB-PR6 also east side land offices covered under rule: 36.11.434(1)(d)	Hiding cover in riparian areas -- Apply constraints for riparian harvest strategy. All RMZs associated with class 1 streams deferred.	Stream layer(s) and SLI stand data	All forest lands including both HCP and non-HCP lands	Constraint parameters are those defined for aquatic buffers -- taken out of commercial SLI acres and not included as operable. All Class 1 aquatic buffers deferred. Widths: 120 ft. SWN, STW, LIB; 100 ft. MSLA, KU, CLW, PLNS, HAM; 80 ft. East Side and ANA. Class 2 and 3 -- 25 ft. deferrals with the remaining 25 ft. of the 50 ft. buffer harvested.
Grizzly Bear	HCP, GB-RZ2	100 ft. Visual Screening buffers along open roads - no clear-cut or seed-tree treatments may occur in these buffers.	Road layer, SLI stand data, recovery zone boundary, and NROH CYE boundary	All Recovery Zone lands and CYE NROH.	No notes
Grizzly Bear	ARM 36.11.432(1)(d)	34,363 commercial acres of Core deferred from harvest.	Grizzly Bear Core polygon layer and SLI stand data	Stillwater Block	No notes
Canada Lynx	HCP, LY-HB2(2) and ARM 36.11.411	In lynx habitat, retain average of 2 snags and 2 live recruitment tree/acre >21 inches DBH on warm and moist, and wet habitat type groups; and 1 snags and 1 live recruitment tree/acre.	SLI stand data and/or forest stand polygon layer.	All forested state trust lands	Uses constraint approach similar to 2004. Base constraint on expected trees/ac and volume retained in live recruitment trees by prescription applied in model. Constraint applied to green trees given high defect in most large, dead snags that are retained.

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
Canada Lynx	HCP, LY-HB6	At each Land Office, retain at least 65% total potential class lynx habitat in the suitable habitat condition. Suitable habitat consists of stands in appropriate habitat types that possess at least 40% total canopy closure in sapling, pole and/or saw-timber classes.	Modeled lynx habitat fields in SLI and forest stand polygon layer.	All forested scattered lands outside of lynx LMA's	Because the model could not grow canopy cover for in-growth over time in a manner that would closely reflect reality, a basal area requirement of 60 square feet was used in lieu of the 40% canopy cover requirement.
Canada Lynx	HCP, LY-LM1	At scale of <u>each</u> LMA, retain at least 65% total potential class lynx habitat in the suitable habitat condition. Suitable habitat consists of stands in appropriate habitat types that possess at least 40% total canopy closure in sapling, pole and/or saw-timber classes.	Modeled lynx habitat fields in SLI and forest stand polygon layer, and LMA polygon layer.	Applies to lynx habitat on DNRC lands within lynx LMA's	Because the model could not grow canopy cover for in-growth over time in a manner that would closely reflect reality, a basal area requirement of 60 was used in lieu of the 40% canopy cover requirement.
Canada Lynx	HCP, LY-LM2	No more than 15% of total potential habitat class may be converted to non-suitable class in each decade.	Modeled lynx habitat fields in SLI and forest stand polygon layer, and LMA polygon layer.	Applies to lynx habitat on DNRC lands within lynx LMA's	Also viewed as a limit on even-aged harvest acres per decade. Once that limit is hit, only uneven-aged regimes can be selected.

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
Canada Lynx	HCP, LY-LM3(1)	At scale of <u>each LMA</u> , retain at least 20% total potential class lynx habitat in the winter foraging habitat condition. Winter foraging habitat consists of saw-timber stands that possess at least 40% total stand canopy closure and contain AF, SP, and/or GF.	Modeled lynx habitat fields in SLI and forest stand polygon layer, and LMA polygon layer.	Applies to lynx habitat on DNRC lands within lynx LMA's	Because the model could not grow canopy cover for in-growth over time in a manner that would closely reflect reality, a basal area requirement of 60 was used in lieu of the 40% canopy cover requirement.
Canada Lynx	ITP constraint	No more than 1,200 acres of lynx habitat can be pre-commercially thinned annually.	Modeled lynx habitat fields in SLI and forest stand polygon layer, and LMA polygon layer.	Applies to lynx habitat on DNRC lands within lynx LMA's	No notes
Bald Eagle	36.11.429 (1)(c)(ii) and (d)(ii)	Allow no harvest prescriptions that would result in residual basal areas lower than 60 sq. feet.	Nest tree point locations and SLI data	Buffer out from nest point to 800m on DNRC lands.	This simplified constraint requires a moderate threshold of cover retention across the entire primary use area. This approach "averages" the harvest across the entire 800m buffer area and would take into account required heavy retention in nest site areas, but allows for more volume removal at greater distance from the nest site area.

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
Snags	36.11.411	Retain average of 2 snags and 2 live recruitment tree/acre >21 inches DBH on warm and moist, and wet habitat type groups; and 1 snags and 1 live recruitment tree/acre.	NA	NA	Uses constraint approach similar to 2004. Base constraint on expected trees/ac and volume retained in live recruitment trees by prescription applied in model. Constraint applied to green trees given high defect in most large, dead snags that are retained.

Table 34: Species and Associated Conservation Measures Not Considered

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
Grizzly Bear	HCP, GB-ST2	19,000 acres of class A lands under 4 year active/8 year rest mgmt.	Class A lands polygon layer and SLI stand data	Stillwater Block	A constraint for this requirement was not applied in 2015 or 2004. The SYC team discussed the need for a constraint to address HCP, GB-ST2 and concluded that given the presence of interspersed deferred acres in these zones and ability to manage in commercial 4-year windows, no constraint was necessary.
Grizzly Bear	ARM 36.11.431(1)(a)	55,000 of grizzly bear management units under 3 year active/6 year rest mgmt.	Grizzly bear subunit polygon layer and SLI stand data	Swan River State Forest	Did not include a constraint for this in 2015 or 2004. The SYC team discussed the need for a constraint to address this ARM and concluded that given the ability to manage in commercial 3-year windows

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
					and winter period, no constraint was necessary.
Grizzly Bear	HCP, GB-SC2	33,300 acres of scattered parcels in recovery zones and CYE NROH under 4 year active/8 year rest mgmt.	Scattered parcels recovery zone layer, CYE NROH, and SLI stand data	All HCP scattered lands in recovery zones and CYE NROH	The SYC team discussed the need for a constraint to address HCP, GB-SC2 and concluded that given the ability to manage in commercial 4-year windows and winter period, no constraint was necessary. The smaller geographic area of "a parcel" compared to a larger subunit makes it inherently less necessary to revisit a section within an 8 year rest window.
Canada Lynx	HCP, LY-HB5 and Fisher ARM 36.11.440(c)	Provide for habitat connectivity of mature forest cover across 3rd order drainages.	DEM, SLI stand data, forest stand polygon layer.	Ridgetops associated with DNRC forest land.	Considerable subjective analysis would be required for a minimal number of acres constrained. The team concluded that this measure typically would be met in deferrals, RMZs, and through application of allowable prescription percentages by cover type.

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
Canada Lynx	HCP, LY-LM3(2)	For any treated PCT stand in lynx habitat in LMAs, retain 20% of each project area (i.e., total of all PCT units identified for treatment) in an un-thinned condition until they meet saw-timber size class.	Modeled lynx habitat fields in SLI and forest stand polygon layer, and LMA polygon layer.	Applies to lynx habitat on DNRC lands within lynx LMA's	This constraint was deemed unnecessary given that annual budgetary constraints have a predominant functional limit on thinning in DNRC's program. Also, PCT would be allowed unconstrained on all non-lynx forest types, and the minor acreages of retained patches were deemed to have minimal influence on long-term yield.
Fisher	36.11.440	Apply constraints for riparian harvest strategy, old growth, and snags to cover this species. All RMZs associated with class 1 streams deferred.	NA	NA	Addressed through coarse filter management and general application of allowable harvest regimes, riparian harvest strategies, and snag requirements. No additional specific constraint required.
Flammulated Owl	36.11.437	No Constraint Necessary	NA	NA	Addressed through coarse filter management, old growth, and general application of allowable harvest regimes and snag requirements.
Black-Backed Woodpecker	36.11.438	No Constraint Necessary	NA	NA	Addressed through coarse filter management and general application of allowable harvest regimes. The measure is typically met by retaining desirable live and dead trees in burned areas

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
					and intensively burned acreages on inoperable or deferred ground.
Pileated Woodpecker	36.11.439	No Constraint Necessary	NA	NA	Addressed through coarse filter management, old growth, and general application of allowable harvest prescriptions by cover type and snag requirements.
Common Loon	36.11.441	No Constraint Necessary	NA	NA	Harvest-related mitigation requirements are rare and affect a very small number of acres annually on average (i.e., <50 ac per yr.).
Peregrine Falcon	36.11.442	No Constraint Necessary	NA	NA	Harvest-related mitigation requirements are rare and affect a very small number of acres annually on average (i.e., <50 ac per yr.).
Gray Wolf	36.11.430	No Constraint Necessary	NA	NA	No specific forest cover requirements for this species.
Wolverine	n/a	No Constraint Necessary	NA	NA	No specific forest cover requirements for this species, and most limiting habitat areas are relatively non-forested, high elevation zones with persistent snow late into spring.

Species	ARM or HCP Measures	Constraint Description Summary	Related Data Available	Geographic Area Applicable	Notes
Yellow-Billed Cuckoo	n/a	No Constraint Necessary	NA	NA	Suitable habitat for this species in Montana is comprised of cottonwood river bottoms where active timber harvest is not economical and is generally prohibited.
Big Game	36.11.443	No Constraint Necessary	NA	NA	Addressed through coarse filter management and general application of allowable harvest prescriptions by cover type.

15 Appendix O: Growth Rates by Land Office

In this section, the estimated growth rates in board feet per acre per year determined by the calculation are displayed for each Land Office. Growth rates from other published sources are also included for purposes of comparison.

Table 35: Estimated and Historic Growth Rates (bf/ac/yr)

Area	2020 SYC Grow Only	2020 SYC Bio Gross	2014 FIA ²⁵	1989 FIA ²⁶	Timber Resources Publications ²⁷
Statewide	123	123	72	126	111
NW	171	176	129	151	146
